Practice, Engage, and Assess with MyEconLab®

- **Pearson eText**—The Pearson eText gives students access to their textbook anytime, anywhere. In addition to note-taking, highlighting, and bookmarking, the Pearson eText offers interactive and sharing features. Students actively read and learn, through embedded and auto-graded practice, real-time data-graphs, animations, author videos, and more. Instructors can share comments or highlights, and students can add their own, for a tight community of learners in any class.

- **Practice**—Algorithmically generated homework and study plan exercises with instant feedback ensure varied and productive practice, helping students improve their understanding and prepare for quizzes and tests. Draw-graph exercises encourage students to practice the language of economics.

- **Learning Resources**—Personalized learning aids such as Help Me Solve This problem walkthroughs, Teach Me explanations of the underlying concept, and figure Animations provide on-demand help when students need it most.

- **Adaptive Study Plan**—Monitors each student's progress and offers a continuously personalized study plan based on his or her own homework, quiz, and test results. Includes unlimited practice exercises and the opportunity to prove mastery through quizzes based on recommended learning objectives.

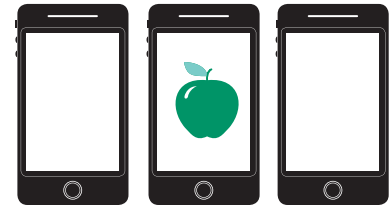

- **Dynamic Study Modules**—With a focus on key topics, these modules work by continuously assessing student performance and activity in real time and, using data and analytics, provide personalized content to reinforce concepts that target each student's particular strengths and weaknesses.

- **Digital Interactives**—Focused on a single core topic and organized in progressive levels, each interactive immerses students in an assignable and auto-graded activity. Digital Interactives are also engaging lecture tools for traditional, online, and hybrid courses, many incorporating real-time data, data displays, and analysis tools for rich classroom discussions.

Practice, Engage, and Assess with MyEconLab[®]

- **Learning Catalytics**—Generates classroom discussion, guides lectures, and promotes peer-to-peer learning with real-time analytics. Students can use any device to interact in the classroom, engage with content, and even draw and share graphs.

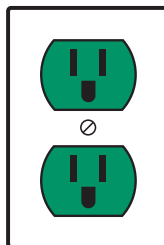

- **Real-Time Data Analysis Exercises**—Using current macro data to help students understand the impact of changes in economic variables, Real-Time Data Analysis Exercises communicate directly with the Federal Reserve Bank of St. Louis's FRED[®] site and update as new data are available.

- **Current News Exercises**—Every week, current microeconomic and macroeconomic news stories, with accompanying exercises, are posted to MyEconLab. Assignable and auto-graded, these multi-part exercises ask students to recognize and apply economic concepts to real-world events.

- **Experiments**—Flexible, easy-to-assign, auto-graded, and available in Single and Multiplayer versions, Experiments in MyEconLab make learning fun and engaging.

- **Reporting Dashboard**—View, analyze, and report learning outcomes clearly and easily. Available via the Gradebook and fully mobile-ready, the Reporting Dashboard presents student performance data at the class, section, and program levels in an accessible, visual manner.

- **LMS Integration**—Link from any LMS platform to access assignments, rosters, and resources, and synchronize MyLab grades with your LMS gradebook. For students, new direct, single sign-on provides access to all the personalized learning MyLab resources that make studying more efficient and effective.

- **Mobile Ready**—Students and instructors can access multimedia resources and complete assessments right at their fingertips, on any mobile device.

ABOUT THE AUTHORS

Glenn Hubbard, policymaker, professor, and researcher.

R. Glenn Hubbard is the dean and Russell L. Carson Professor of Finance and Economics in the Graduate School of Business at Columbia University and professor of economics in Columbia's Faculty of Arts and Sciences. He is also a research associate of the National Bureau of Economic Research and a director of Automatic Data Processing, Black Rock Closed-End Funds, and MetLife. He received his Ph.D. in economics from Harvard University in 1983. From 2001 to 2003, he served as chairman of the White House Council of Economic Advisers

and chairman of the OECD Economic Policy Committee, and from 1991 to 1993, he was deputy assistant secretary of the U.S. Treasury Department. He currently serves as co-chair of the nonpartisan Committee on Capital Markets Regulation. Hubbard's fields of specialization are public economics, financial markets and institutions, corporate finance, macroeconomics, industrial organization, and public policy. He is the author of more than 100 articles in leading journals, including *American Economic Review*, *Brookings Papers on Economic Activity*, *Journal of Finance*, *Journal of Financial Economics*, *Journal of Money, Credit, and Banking*, *Journal of Political Economy*, *Journal of Public Economics*, *Quarterly Journal of Economics*, *RAND Journal of Economics*, and *Review of Economics and Statistics*. His research has been supported by grants from the National Science Foundation, the National Bureau of Economic Research, and numerous private foundations.

Tony O'Brien, award-winning professor and researcher.

Anthony Patrick O'Brien is a professor of economics at Lehigh University. He received his Ph.D. from the University of California, Berkeley, in 1987. He has taught principles of economics for more than 20 years, in both large sections and small honors classes. He received the Lehigh University Award for Distinguished Teaching. He was formerly the director of the Diamond Center for Economic Education and was named a Dana Foundation Faculty Fellow and Lehigh Class of 1961 Professor of Economics. He has been a visiting professor at the University of

California, Santa Barbara, and the Graduate School of Industrial Administration at Carnegie Mellon University. O'Brien's research has dealt with issues such as the evolution of the U.S. automobile industry, the sources of U.S. economic competitiveness, the development of U.S. trade policy, the causes of the Great Depression, and the causes of black–white income differences. His research has been published in leading journals, including *American Economic Review*, *Quarterly Journal of Economics*, *Journal of Money, Credit, and Banking*, *Industrial Relations*, *Journal of Economic History*, and *Explorations in Economic History*. His research has been supported by grants from government agencies and private foundations.

PREFACE

Our approach in this new edition remains what it was in the first edition, published more than 10 years ago: To provide students and instructors with an economics text that delivers complete economics coverage with many real-world business examples. Our goal has been to teach economics in a “widget-free” way by using real-world business and policy examples. We are gratified by the enthusiastic response from students and instructors who have used the first five editions of this book and who have made it one of the best-selling economics textbooks on the market.

Much has happened in the U.S. and world economies since we prepared the previous edition. We have incorporated many of these developments in the new real-world examples in this edition and also in the digital resources.

Digital Resources

While our basic approach of placing applications in the forefront of the discussion remains the same, this new edition has been thoroughly revised. We have a wide array of digital resources for students and instructors to use with either the eText version of the book or the MyEconLab supplement to the printed text. Below is an overview. Please see Preface pages 43–47 for more details.

Digital Features Located in MyEconLab

MyEconLab is a unique online course management, testing, and tutorial resource. It is included with the eText version of the book or as a supplement to the print book. Students and instructors will find the following online resources to accompany the sixth edition:

- **Videos.** There are more than 100 *Making the Connection* features in the book that provide real-world reinforcement of key concepts. Each feature is accompanied by a two- or three-minute video of the author explaining the key point of that *Making the Connection*. Related assessment is included with each video, so students can test their understanding. The goal of these videos is to summarize key content and bring the applications to life. In our experience, many students benefit from this type of online learning and assessment.
- **Concept Checks.** Each section of each learning objective concludes with an online Concept Check that contains one or two multiple-choice, true/false, or fill-in questions. These checks act as “speed bumps” that encourage students to stop and check their understanding of fundamental terms and concepts before moving on to the next section. The goal of this digital resource is to help students assess their progress on a section-by-section basis, so they can be better prepared for homework, quizzes, and exams.
- **Animations.** Graphs are the backbone of introductory economics, but many students struggle to understand and work with them. Each of the 267 numbered figures in the text has a supporting animated version online. The goal of this digital resource is to help students understand shifts in curves, movements along curves, and changes in equilibrium values. Having an animated version of a graph helps students who have difficulty interpreting the static version in the printed text. Graded practice exercises are included with the animations. In our experience, many students benefit from this type of online learning.
- **Interactive Solved Problems.** Many students have difficulty applying economic concepts to solving problems. The goal of this digital resource is to help students overcome this hurdle by giving them a model of how to solve an economic problem by breaking it down step by step. Each of the 60 *Solved Problems* in the printed text is accompanied by a similar problem online, so students can have more practice and build their

problem-solving skills. These interactive tutorials help students learn to think like economists and apply basic problem-solving skills to homework, quizzes, and exams. The goal is for students to build skills they can use to analyze real-world economic issues they hear and read about in the news. Each *Solved Problem* in MyEconLab and the digital eText also includes at least one additional graded practice exercise for students.

- **Graphs Updated with Real-Time Data from FRED.** Approximately 25 graphs are continuously updated online with the latest available data from FRED (Federal Reserve Economic Data), which is a comprehensive, up-to-date data set maintained by the Federal Reserve Bank of St. Louis. Students can display a pop-up graph that shows new data plotted in the graph. The goal of this digital feature is to help students understand how to work with data and understand how including new data affects graphs.
- **Interactive Problems and Exercises Updated with Real-Time Data from FRED.** The end-of-chapter problems in select chapters include *Real-Time Data Exercises* that use the latest data from FRED. The book contains more than 50 of these exercises. The goals of this digital feature are to help students become familiar with this key data source, learn how to locate data, and develop skills in interpreting data.

New to the Sixth Edition Chapters

- All companies in the chapter openers have been either replaced with new companies or updated with current information.
- Chapters 1–4 include new *An Inside Look* news articles and analyses to help students apply economic thinking to current events and policy debates. Additional news articles and analyses are updated weekly on MyEconLab.
- There are 38 new *Making the Connection* features to help students tie economic concepts to current events and policy issues.
- There are 16 new *Solved Problems*. This feature helps students break down and answer economic problems step by step.

New Chapter Openers, *Making the Connections*, *Solved Problems*, and *Inside Looks*

Here are the new or heavily revised chapter-opening business cases and accompanying *Inside Look* news articles. The business or issue introduced in the chapter opener is revisited within the chapter in either a *Making the Connection* or a *Solved Problem*. The following are new to this edition. Please see the detailed table of contents for the list of features for all chapters.

Chapter 1, “Economics: Foundations and Models,” opens with a new discussion of whether smart devices will revolutionize health care and closes with *An Inside Look* newspaper article and analysis of how Google is adding to its growing list of technological innovations by partnering with Swiss pharmaceutical company Novartis to develop smart contact lenses to help patients manage diabetes. New *Solved Problem 1.1* examines how managers at medical technology firm OraSure use marginal analysis to make an advertising decision. A new *Making the Connection* examines how opportunity costs can help us understand why many students have stopped attending college football games.

Chapter 2, “Trade-offs, Comparative Advantage, and the Market System,” opens with a new discussion of the manufacturing decisions managers at Tesla Motors face and closes with *An Inside Look* that discusses the resources Apple has assembled to meet an aggressive plan to develop and produce an electric vehicle as early as 2020. A new *Making the Connection* uses Sir Arthur Conan Doyle’s legendary character Sherlock Holmes to illustrate copyright laws for books and movies.

Chapter 3, “Where Prices Come From: The Interaction of Demand and Supply,” opens with a new discussion of the market for smartwatches and closes with *An Inside Look* that examines how the Apple smartwatch is inspiring the development of other wearable devices. There are three new *Making the Connections*: “Are Smartwatches Substitutes for Smartphones?”; “Tough Times for Big Macs and Golf”; and “Demand and Supply Trashes Plastic Recycling.”

Chapter 4, “Economic Efficiency, Government Price Setting, and Taxes,” opens with an updated discussion of how Airbnb and the sharing economy affects rent control policy in San Francisco and closes with *An Inside Look* that examines why government officials in Malibu, California, imposed a tax on short-term rentals of apartments booked through Airbnb. A new *Making the Connection* examines why investors expect Uber to be very profitable.

Chapter 5, “Externalities, Environmental Policy, and Public Goods,” opens with a new discussion of President Obama’s Clean Power Plan. A new *Making the Connection* uses the frequent conflicts between passengers over reclining airline seats to illustrate property rights.

Chapter 6, “Elasticity: The Responsiveness of Demand and Supply,” opens with a revised and updated discussion of the price elasticity of gasoline. A new *Making the Connection* discusses why Amazon cares about price elasticity.

Chapter 7, “The Economics of Health Care,” opens with a new discussion of how the *National Health and Hospitals Reform Commission*, established in 2008, and the *National Health Reform Agreement*, signed in 2011, helped the Australian government to conjoin individual and collective action to introduce good health care in the country. New *Solved Problem 7.4* shows students how to use the demand and supply model to explain changes in health care spending. A new *Making the Connection* discusses the increasing importance of health care in the U.S. economy.

Chapter 8, “Firms, the Stock Market, and Corporate Governance,” opens with a new discussion of Twitter and the benefits and costs of becoming a publicly owned firm. New *Solved Problem 8.2* analyzes why Warren Buffett likes mutual funds, and new *Solved Problem 8.4* discusses whether Dodd-Frank will improve corporate governance. There are two new *Making the Connections*: “Why Are Fewer Young People Starting Businesses?” and “Why Are Many People Poor Stock Market Investors?”

Chapter 9, “Comparative Advantage and the Gains from International Trade,” opens with a new discussion of President Obama, Nike, and the Trans-Pacific Partnership (TPP). There are three new *Making the Connections*: “Would New Balance Be Helped or Hurt by the Trans-Pacific Partnership?”; “Smoot-Hawley, the Politics of Tariffs, and Protecting a Vanishing Industry”; and “Protecting Consumer Health or Protecting U.S. Firms from Competition?”

Chapter 10, “Consumer Choice and Behavioral Economics,” opens with an updated discussion of a failed pricing strategy at J. C. Penney. A new *Making the Connection* discusses whether Uber is price gouging by charging more when demand for rides is high.

Chapter 11, “Technology, Production, and Costs,” opens with a new discussion of MOOCs (massive open online courses). A new *Making the Connection* explains how UPS adopted new technology to deliver more packages with the same number of workers and planes. A new *Solved Problem* in the appendix discusses how firms respond to differences in input price ratios.

Chapter 12, “Firms in Perfectly Competitive Markets,” opens with a new discussion of cage-free eggs. New *Solved Problem 12.4* examines when managers should shut down an oil well.

Chapter 13, “Monopolistic Competition: The Competitive Model in a More Realistic Setting,” opens with a new discussion of the sources of Chipotle Mexican Grill’s success. There are two new *Making the Connections*: “Is the Trend toward Healthy Eating

a Threat to Chipotle’s Market Niche?” and “Are All Cupcakes the Same?” New *Solved Problem 13.3* examines Buffalo Wild Wings’ strategy to differentiate its restaurants.

Chapter 14, “Oligopoly: Firms in Less Competitive Markets,” opens with a new discussion of Apple, Spotify, and the music streaming revolution. The chapter includes two new *Making the Connections*: “Hard Times in Atlantic City” and “Do Airlines Collude on Capacity to Keep Prices High?”

Chapter 15, “Monopoly and Antitrust Policy,” includes a new *Making the Connection* that examines whether the National Collegiate Athletic Association (NCAA) should be considered a monopoly. New *Solved Problem 15.5* shows students how to determine a pricing strategy for a MOOC (massive open online course).

Chapter 16, “Pricing Strategy,” opens with new coverage of Walt Disney’s MagicBands and how the company uses “big data” to help determine pricing. A new *Making the Connection* illustrates how clothing manufacturers can segment their sales by using outlet stores.

Chapter 17, “The Markets for Labor and Other Factors of Production,” opens with a new discussion of how Rio Tinto Mines has used robots to replace some workers. There are three new *Making the Connections*: “Is Investing in a College Education a Good Idea?”; “Should You Fear the Effect of Robots on the Labor Market?”; and “Technology and the Earnings of ‘Superstars.’”

Chapter 18, “Public Choice, Taxes, and the Distribution of Income,” opens with updated coverage of the debate about tax policy among the 2016 presidential candidates and includes new *Solved Problem 18.4* about income mobility.

Chapter 19, “GDP: Measuring Total Production and Income,” opens with updated coverage of how the business cycle affects Ford Motor Company and includes a new *Making the Connection* about how calculating GDP changes the way the standard of living in Nigeria is measured.

Chapter 20, “Unemployment and Inflation,” opens with a new discussion of JPMorgan’s 2015 decision to lay off workers. There are two new *Making the Connections*: “Eight Million Workers Are Missing!” and “How Should We Categorize Unemployment at JPMorgan Chase?” New *Solved Problem 20.5* shows students how to use data to calculate real hourly wages.

Chapter 21, “Economic Growth, the Financial System, and Business Cycles,” opens with a new discussion of how Corning has experienced long-run growth while experiencing the ups and downs of the business cycle. New *Solved Problem 21.1* focuses on the connection between productivity and prosperity, and new *Solved Problem 21.2* shows students how to apply the loanable funds model to analyze the effect of budget deficits.

Chapter 22, “Long-Run Economic Growth: Sources and Policies,” opens with a new discussion of whether economic reforms will help to increase Mexico’s growth rate and includes a new *Making the Connection* that compares economic growth in Mexico and China.

Chapter 23, “Aggregate Expenditure and Output in the Short Run,” opens with an updated opener on the effects of fluctuations in aggregate expenditure on Intel and includes a new *Making the Connection* about the link between student loans and the number of young people purchasing homes.

Chapter 24, “Aggregate Demand and Aggregate Supply Analysis,” opens with a new discussion of the effect of the business cycle on Delta Airlines and includes a new *Making the Connection* that discusses how unusually long it took following the 2007–2009 recession for real GDP and employment to return to the levels achieved at the business cycle peak.

Chapter 25, “Money, Banks, and the Federal Reserve System,” opens with a new discussion of the 2015 banking crisis in Greece and includes a new *Making the Connection* on peer-to-peer lending.

Chapter 26, “Monetary Policy,” opens with a new discussion of the connection between monetary policy and borrowers in Europe paying negative nominal interest rates on bank loans. Two new *Making the Connections* examine the connection between central bank policies of quantitative easing and negative interest rates, and why the Federal Reserve usually ignores fluctuations in food and energy prices.

Chapter 27, “Fiscal Policy,” opens with a new discussion of the effects of federal government spending to rebuild a highway leading to the Golden Gate Bridge. A new *Making the Connection* discusses whether macroeconomic policy is too dependent on the Federal Reserve. New *Solved Problem 27.6* analyzes the effects of the Greek government attempting to balance its budget during a recession.

Chapter 28, “Inflation, Unemployment, and Federal Reserve Policy,” opens with a new discussion of why a company like Goodyear is concerned about monetary policy. A new *Making the Connection* examines whether it is important for the Fed to provide the public with accurate guidance on the future of monetary policy.

Chapter 29, “Macroeconomics in an Open Economy,” opens with a new discussion on how fluctuations in the exchange rate affect IBM’s profits. A new *Making the Connection* examines whether a strong dollar is a good for the U.S. economy. New *Solved Problem 29.2* analyzes how Subaru is affected by fluctuations in the value of the yen.

Chapter 30, “The International Financial System,” opens with a new discussion about how Bayer deals with fluctuating exchange rates. There are two new *Making the Connections*: “Greece and Germany: Diverse Economies, Common Currency” and “The Chinese Yuan: The World’s Most Controversial Currency.”

Other Changes to Chapters

- In Chapter 18, Section 18.4, “Income Distribution and Policy,” has been reorganized and includes the new subsection “Policies to Reduce Income Inequality.”
- Chapter 21 includes a new section that discusses why firms like Corning are particularly vulnerable to fluctuations in demand during the business cycle.
- Chapter 28 includes a new final section that covers the debate over the future of the Fed.
- We have added the following five new tables to present information in an easy-to-read format: Table 1.1, “Issues in Microeconomics and Macroeconomics”; Table 15.1, “Timeline of the EU Competition Law”; Table 17.3, “Differences in Education among Ethnic Groups,” which presents data on the education levels for three ethnic groups; Table 18.8, “The Effect of Taxes and Transfers on the Distribution of Household Income in the United States”; and Table 26.3, “Treasury and Fed Actions at the Beginning of the Financial Crisis.”
- To make room for the new content described earlier, we have cut approximately 35 *Making the Connections* and 10 *Solved Problems* from the previous edition and transferred some of them to the book’s *Instructor’s Manual*, where they are available for instructors who wish to continue using them.
- Figures and tables have been updated with the latest data available.
- Many of the end-of-chapter problems have been either replaced or updated. To most chapters, we have added one or two new problems that include graphs for students to analyze. Select chapters have a category called *Real-Time Data Exercises*. Some of these exercises have been updated for this new edition.
- Finally, we have gone over the text literally line by line, tightening the discussion, rewriting unclear points, and making many small changes. We are grateful to the many instructors and students who made suggestions for improvements in the previous edition. We have done our best to incorporate as many of those suggestions as possible.

The Foundation:

Contextual Learning and Modern Organization

We believe a course is a success if students can apply what they have learned to both their personal lives and their careers, and if they have developed the analytical skills to understand what they read in the media. That's why we explain economic concepts by using many real-world business examples and applications in the chapter openers, graphs, *Making the Connection* features, *An Inside Look* features, and end-of-chapter problems. This approach helps both business majors and liberal arts majors become educated consumers, voters, and citizens. In addition to our widget-free approach, we have a modern organization and place interesting policy topics early in the book to pique student interest.

Microeconomics

We are convinced that students learn to apply economic principles best if they are taught in a familiar context. Whether they become artists, social workers, bankers, or government employees, students benefit from understanding economics. Though business students will have many opportunities to see economic principles in action in various courses, liberal arts students may not. We therefore use many diverse real-world business and policy examples to illustrate economic concepts and develop educated consumers, voters, and citizens. Here are a few highlights of our approach to microeconomics:

- **A strong set of introductory chapters.** The introductory chapters provide students with a solid foundation in the basics. We emphasize the key ideas of marginal analysis and economic efficiency. In Chapter 4, "Economic Efficiency, Government Price Setting, and Taxes," we use the concepts of consumer and producer surplus to measure the economic effects of price ceilings and price floors as they relate to the familiar examples of rental properties and the minimum wage. (We revisit consumer and producer surplus in Chapter 9, "Comparative Advantage and the Gains from International Trade," where we discuss outsourcing and analyze government policies that affect trade; in Chapter 15, "Monopoly and Antitrust Policy," where we examine the effect of market power on economic efficiency; and in Chapter 16, "Pricing Strategy," where we examine the effect of firm pricing policy on economic efficiency.) In Chapter 8, "Firms, the Stock Market, and Corporate Governance," we provide students with a basic understanding of how firms are organized, raise funds, and provide information to investors. We also illustrate how in a market system entrepreneurs meet consumer wants and efficiently organize production.
- **Early coverage of policy issues.** To expose students to policy issues early in the course, we discuss health care policy in Chapter 1, "Economics: Foundations and Models"; rent control and the minimum wage in Chapter 4, "Economic Efficiency, Government Price Setting, and Taxes"; air pollution, global warming, and public goods in Chapter 5, "Externalities, Environmental Policy, and Public Goods"; government policy toward illegal drugs in Chapter 6, "Elasticity: The Responsiveness of Demand and Supply"; and health care policy in Chapter 7, "The Economics of Health Care."
- **Complete coverage of monopolistic competition.** We devote a full chapter, Chapter 13, "Monopolistic Competition: The Competitive Model in a More Realistic Setting," to monopolistic competition prior to covering oligopoly and monopoly in Chapter 14, "Oligopoly: Firms in Less Competitive Markets," and Chapter 15, "Monopoly and Antitrust Policy." Although many instructors cover monopolistic competition very briefly or dispense with it entirely, we think it is an overlooked tool for reinforcing the basic message of how markets work in a context that is much more familiar to students than are the agricultural examples that dominate other discussions of perfect competition. We use the monopolistic competition model to introduce the

downward-sloping demand curve material usually introduced in a monopoly chapter. This approach helps students grasp the important point that nearly all firms—not just monopolies—face downward-sloping demand curves. Covering monopolistic competition directly after perfect competition also allows for early discussion of topics such as brand management and sources of competitive success. Nevertheless, we wrote the chapter so that instructors who prefer to cover monopoly (Chapter 15, “Monopoly and Antitrust Policy”) directly after perfect competition (Chapter 12, “Firms in Perfectly Competitive Markets”) can do so without loss of continuity.

- **Extensive, realistic game theory coverage.** In Chapter 14, “Oligopoly: Firms in Less Competitive Markets,” we use game theory to analyze competition among oligopolists. Game theory helps students understand how companies with market power make strategic decisions in many competitive situations. We use familiar companies such as Apple, Amazon, Dell, Spotify, and Walmart in our game theory applications.
- **Unique coverage of pricing strategy.** In Chapter 16, “Pricing Strategy,” we explore how firms use pricing strategies to increase profits. Students encounter pricing strategies everywhere—when they buy a movie ticket, book a flight for spring break, or research book prices online. We use these relevant, familiar examples to illustrate how companies use strategies such as price discrimination, cost-plus pricing, and two-part tariffs.

Macroeconomics

Students come to study macroeconomics with a strong interest in understanding events and developments in the economy. We try to capture that interest and develop students’ economic intuition and understanding. We present macroeconomics in a way that is modern and based in the real world of business and economic policy. And we believe we achieve this presentation without making the analysis more difficult. We avoid the recent trend of using simplified versions of intermediate models, which are often more detailed and complex than what students need to understand the basic macroeconomic issues. Instead, we use a more realistic version of the familiar aggregate demand and aggregate supply model to analyze short-run fluctuations and monetary and fiscal policy. We also avoid the “dueling schools of thought” approach often used to teach macroeconomics at the principles level. We emphasize the many areas of macroeconomics where most economists agree. And we present throughout real business and policy situations to develop students’ intuition. Here are a few highlights of our approach to macroeconomics:

- **A broad discussion of macro statistics.** Many students pay at least some attention to the financial news and know that the release of statistics by federal agencies can cause movements in stock and bond prices. A background in macroeconomic statistics helps clarify some of the policy issues encountered in later chapters. In Chapter 19, “GDP: Measuring Total Production and Income,” and Chapter 20, “Unemployment and Inflation,” we provide students with an understanding of the uses and potential shortcomings of the key macroeconomic statistics, without getting bogged down in the minutiae of how the statistics are constructed. So, for instance, we discuss the important differences between the payroll survey and the household survey for understanding conditions in the labor market. We explain why financial markets react more strongly to news from the payroll survey. We provide a discussion of the employment–population ratio, which is not covered in some other books but which many economists regard as a key measure of labor market performance. Chapter 26, “Monetary Policy,” discusses why the Federal Reserve prefers to measure inflation using the core personal consumption expenditures price index rather than the consumer price index.
- **Early coverage of long-run topics.** We place key macroeconomic issues in their long-run context in Chapter 21, “Economic Growth, the Financial System, and Business Cycles,” and Chapter 22, “Long-Run Economic Growth: Sources and Policies.”

Chapter 21 puts the business cycle in the context of underlying long-run growth and discusses what actually happens during the phases of the business cycle. We believe this material is important if students are to have the understanding of business cycles they will need to interpret economic events; this material is often discussed only briefly or omitted entirely in other books. We know that many instructors prefer to have a short-run orientation to their macro courses, with a strong emphasis on policy. Accordingly, we have structured Chapter 21 so that its discussion of long-run growth is sufficient for instructors who want to move quickly to short-run analysis. Chapter 22 uses a simple neoclassical growth model to explain important growth issues. We apply the model to topics such as the decline of the Soviet economy, the long-run prospects for growth in China, the implications of the slowdown in productivity growth for the U.S. economy, and the failure of many developing countries to sustain high growth rates. *And we challenge students with the discussion “Why Isn’t the Whole World Rich?”*

- **A dynamic model of aggregate demand and aggregate supply.** We take a fresh approach to the standard aggregate demand and aggregate supply (AD–AS) model. We realize there is no good, simple alternative to using the AD–AS model when explaining movements in the price level and in real GDP. But we know that more instructors are dissatisfied with the AD–AS model than with any other aspect of the macro principles course. The key problem, of course, is that AD–AS is a static model that attempts to account for dynamic changes in real GDP and the price level. Our approach retains the basics of the AD–AS model but makes it more accurate and useful by making it more dynamic. We emphasize two points: (1) Changes in the position of the short-run (upward-sloping) aggregate supply curve depend mainly on the state of expectations of the inflation rate and (2) the existence of growth in the economy means that the long-run (vertical) aggregate supply curve shifts to the right every year. This “dynamic” AD–AS model provides students with a more accurate understanding of the causes and consequences of fluctuations in real GDP and the price level. We introduce this model in Chapter 24 and use it to discuss monetary policy in Chapter 26, “Monetary Policy,” and fiscal policy in Chapter 27, “Fiscal Policy.” The material on dynamic AD–AS is presented in self-contained sections in Chapters 24, 26, and 27, so instructors may safely omit the sections on the dynamic AD–AS model without any loss in continuity to the discussion of macroeconomic theory and policy.
- **Extensive coverage of monetary policy.** Because of the central role monetary policy plays in the economy and in students’ curiosity about business and financial news, we devote two chapters—Chapter 26, “Monetary Policy,” and Chapter 28, “Inflation, Unemployment, and Federal Reserve Policy”—to the topic. We emphasize the issues involved in the Fed’s choice of monetary policy targets, and we include coverage of the Taylor rule. We also cover the debate over the Fed’s policies, including recent proposals in Congress to reduce the Fed’s independence.
- **Coverage of both the demand-side and supply-side effects of fiscal policy.** Our discussion of fiscal policy in Chapter 27, “Fiscal Policy,” carefully distinguishes between automatic stabilizers and discretionary fiscal policy. We also provide significant coverage of the supply-side effects of fiscal policy.
- **A self-contained but thorough discussion of the Keynesian income–expenditure approach.** The Keynesian income–expenditure approach (the “45°-line diagram,” or “Keynesian cross”) is useful for introducing students to the short-run relationship between spending and production. Many instructors, however, prefer to omit this material. Therefore, we use the 45°-line diagram only in Chapter 23, “Aggregate Expenditure and Output in the Short Run.” The discussions of monetary and fiscal policy in Chapter 26, “Monetary Policy,” and Chapter 27, “Fiscal Policy,” respectively, uses only the AD–AS model, making it possible to omit Chapter 23.

- **Extensive international coverage.** We include three chapters devoted to international topics: Chapter 9, “Comparative Advantage and the Gains from International Trade,” Chapter 29, “Macroeconomics in an Open Economy,” and Chapter 30, “The International Financial System.” Having a good understanding of the international trading and financial systems is essential to understanding the macroeconomy and to satisfying students’ curiosity about the economic world around them. In addition to the material in our three international chapters, we weave international comparisons into the narratives of several other chapters, including our discussion of labor market policies in Chapter 28, “Inflation, Unemployment, and Federal Reserve Policy,” and central banking in Chapter 25, “Money, Banks, and the Federal Reserve System.”
- **Flexible chapter organization.** Because we realize that there are a variety of approaches to teaching principles of macroeconomics, we have structured our chapters for maximum flexibility. For example, our discussion of long-run economic growth in Chapter 21, “Economic Growth, the Financial System, and Business Cycles,” makes it possible for instructors to omit the more thorough discussion of these issues in Chapter 22, “Long-Run Economic Growth: Sources and Policies.” Our discussion of the Keynesian 45°-line diagram is confined to Chapter 23, “Aggregate Expenditure and Output in the Short Run,” so that instructors who do not use this approach can proceed directly to aggregate demand and aggregate supply analysis in Chapter 24, “Aggregate Demand and Aggregate Supply Analysis.” While we devote two chapters to monetary policy, the first of these—Chapter 26, “Monetary Policy”—is a self-contained discussion, so instructors may safely omit the material in Chapter 28, “Inflation, Unemployment, and Federal Reserve Policy,” if they choose to. Finally, instructors may choose to omit all three of the international chapters (Chapter 9, “Comparative Advantage and the Gains from International Trade,” Chapter 29, “Macroeconomics in an Open Economy,” and Chapter 30, “The International Financial System”), cover just Chapter 9 on international trade, cover just Chapter 29, or cover Chapters 29 and 30 while omitting Chapter 9. Please refer to the flexibility chart on pages xxvi–xxvii to help select the chapters and order best suited to your classroom needs.

A Real-World, Hands-on Approach to Learning Economics

Business Cases and *An Inside Look* News Articles

Each chapter-opening case provides a real-world context for learning, sparks students' interest in economics, and helps unify the chapter. The case describes an actual company facing a real situation. The company is integrated in the narrative, graphs, and pedagogical features of the chapter. Some of the chapter openers focus on the role of entrepreneurs in developing new products and bringing them to market. For example, Chapter 1 discusses Walter De Brouwer, the founder of Scanadu, which develops smart devices for health care; Chapter 2 discusses Elon Musk of Tesla Motors; and Chapter 13 discusses Steve Ells of Chipotle Mexican Grill. Here are a few examples of companies we discuss in the chapter openers:

- Tesla Motors (Chapter 2, “Trade-offs, Comparative Advantage, and the Market System”)
- Apple (Chapter 3, “Where Prices Come From: The Interaction of Demand and Supply”)
- Twitter (Chapter 8, “Firms, the Stock Market, and Corporate Governance”)
- Delta Airlines (Chapter 24, “Aggregate Demand and Aggregate Supply Analysis”)

How Smart Is Your Watch?

Fashions can change quickly. For many years, most people wore wristwatches. With the popularity of cellphones in the 2000s, many people stopped wearing wristwatches—which was bad news for the watch industry. Once a product falls out of fashion, its sales are unlikely to return to past levels. Will watches prove an exception?

Until recently attempts to have watches do more than tell the time have not been successful. For instance, during the 1980s Texas Instruments and several other firms added small calculators to watches, but sales were limited. In 2004, Microsoft introduced the SPOT watch, which enabled users to receive instant messages, weather reports, and news headlines. But few consumers purchased it so the company stopped production of the watch in 2008. By 2013, several firms had introduced “smartwatches” that enabled users to make phone calls, text, take photos or videos, monitor their heart rates, and calculate calories burned while exercising.

In 2015, Apple introduced the Apple Watch, which combined most of the capabilities of the smartwatches from competing firms with popular features from Apple’s iPhone and iPad, such as access to the iTunes music store and Siri, the voice-activated personal assistant. The Apple Watch was immediately popular, with more than 2.5 million being sold during the first five weeks. These sales were higher than initial sales of Apple’s previous products—the iPod, iPhone, or iPad. More than 25 other firms entered the smartwatch market, hoping to participate in the rapid growth of a hot product.

But there are no guarantees in a market system. Would the Apple Watch and its competitors succeed in bringing the wristwatch back into style, or would they fall like the Texas Instruments calculator watch and the Microsoft SPOT watch? Smartwatches have relatively high prices, are somewhat complicated to use, and have small screens that make it difficult to display photos or maps. Ultimately, the success of the smartwatch is likely to depend on whether consumers like the applications, or “apps,” on these watches and are willing to wear wristwatches again.

The intense competition among firms selling smartwatches is a striking example of how the market responds to changes in technology and consumer tastes. Although competition is not always good news for firms trying to sell products, it is great news for consumers because it increases the available choice of products and lowers the prices consumers pay for those products.

Will You Buy a Smartphone or a Smartwatch?

You use your smartphone mainly to text, read e-mail, and keep track of your appointments. Your smartphone is old, though, and you are thinking of buying a new one ... or should you buy a smartwatch? What factors are most important in your decision: the features of a smartwatch versus a smartphone, or the relative prices of these products? If you know that you are soon going to get a raise at your job, would you be more likely to buy a smartwatch? As you read this chapter, try to answer these questions. You can check your answers against those we provide on page 155 at the end of this chapter.

Apple Watch Inspires Development of Complementary Products

WALL STREET JOURNAL

Don't Underestimate Smartwatches: Wearable Devices Are Poised to Become Central to the Tech Ecosystem

It's important to understand that like the iPhone before it, the Apple Watch isn't at all what its name would imply. Let's call it what it is: a wrist-top computer.

Just as smartphones have become supercomputers in our pockets, the Apple Watch and its many competitors, including Android-powered devices from Motorola and Samsung Electronics, are poised to become something more. And it is their entry into a larger ecosystem of apps and hardware, rather than any one thing that has been shown off recently, that will make them indispensable.

When a company like Google or Apple deliberately creates a place for other companies to sell their own complementary wares, it is called a platform. Apple, more than Google, has mastered this art, having worked hard to give developers the tools to make apps for its mobile devices, plus a controlled environment in which to profit from them.

Fortunately, we don't have to wait for the Apple Watch and its app store to become available to get a glimpse of where things could be going. We have only to look at what pioneering companies in "wearables" are already working on, and then think about how their products will become a part of—or be absorbed

by—the Apple Watch and Android Wear ecosystems.

"The vision of Sensoara is that the garment is the next ultra personal computer," says Sensoara CEO David Vignos. To illustrate this point, he rolls up his pant leg to show me a working prototype of the world's first smart sock.

I know, it sounds ridiculous. But, as he explains, with the help of an iPhone app that visualizes wireless signals sent by minuscule sensors, smart socks in the sock, it is good for runners who want to reduce their chance of injury. It is also potentially useful for monitoring the health of the elderly, since changes in gait are surprisingly predictive of other health issues.

And yes, the smart socks are washable. Sensoara also makes a smart bra and smart shirt, both of which can measure heart rate. And here's where things get really interesting: For all makers of wearables, which until recently have been dominated by the glorified pedometers known as fitness bands, the unique shape of the electrical signals generated by our hearts are a biomarker. Add in a payment terminal not dissimilar from the ones that will roll out with Apple Pay, and the wearers of a Sensoara underwear model could soon find herself verifying payment for her next coffee via technology in her bra. . . .

During Apple's presentation, Apple Vice President Kevin Lynch announced that BMW has developed an app for the Apple Watch that will allow users to lock and unlock their BMW i-series electric vehicles. And Mr. Martin told me that new Bluetooth-enabled locks from companies like Locktron and Kwikset mean that the moment you walk up to a door while sporting a recognized wearable, it can unlock without a touch. . . .

Wearables won't just appeal to fitness nuts and quantified-self geeks. They will appeal to everyone, because they will be the primary, perhaps even the sole way we identify ourselves to a world full of smart objects.

Established makers of wearables have seen this trend and are already getting in front of it. On the same day that Apple announced its watch, Jawbone, maker of the UP wristband, said that it was opening up its quantified-self software so that other firms could connect it with devices other than the UP—including the Apple Watch.

Or in other words, amid the hype about the Apple Watch being a fitness device, or a timepiece, or a status symbol, it is the applications that Apple and others aren't even talking about, the ones that are thought up by countless developers jumping on board the platform, that will make us wonder how we ever got by without them. . . .

Key Points in the Article

The introduction of the Apple Watch has inspired a number of companies to develop products that can utilize the smartwatch's technology. From the wearable technology of Sensoara's sensor-enhanced clothing to convenience items like Bluetooth-enabled door locks, these complementary products will allow consumers to use their smartwatches in new ways, including monitoring their health, making online purchases, and unlocking their front doors. In our technology-driven society, as more products and apps are developed for use with smartwatches, consumers could come to view these watches as a necessity rather than a luxury, which is what happened with smartphones.

Analyzing the News

Smartwatches like the Apple Watch are a part of the relatively new product category of wearable technology. As with smartphones, a large part of the success of smartwatches will depend on the availability of desirable complementary products. One variable that shifts market demand for a product is the price of related goods. If the price of a complement decreases, market demand for the original product will increase, and if the price of a complement increases, market demand for the original product will decrease.

Smart shirts are wearable technology garments that will sync with smartwatches.

so the two products are used together and are therefore complements. Suppose the figure below illustrates supply and demand for smart shirts. In 2014, the most basic smartwatch model had a price of about \$250, and at this price, the demand for smart shirts is represented by demand curve D_1 , with an equilibrium price of P_1 and an equilibrium quantity of Q_1 . If the price of smartwatches increases, this increase would, holding everything else constant, result in a decrease in demand for smart shirts. The demand curve would shift to the left, from D_1 to D_2 , resulting in a decrease in the equilibrium price from P_1 to P_2 and a decrease in the equilibrium quantity from Q_1 to Q_2 .

Conversely, if the price of smartwatches declines, the result will be an increase in demand for smart shirts. The demand curve would shift to the right, from D_1 to D_3 , resulting in an increase in the equilibrium price from P_1 to P_3 and an increase in the equilibrium quantity from Q_1 to Q_3 .

Similarly, more firms will enter the market to compete with existing firms. Some of these firms will offer new products, while other firms will produce goods that compete with existing products. Suppose another apparel manufacturer designs a product to compete with smart shirts. This new product would be a substitute for smart shirts and, all else being equal, changes in the price of this new substitute would change the demand for smart shirts.

In the figure below, an increase in the price of a substitute would, holding everything else constant, increase the demand for smart shirts. The demand curve would shift to the right, from D_1 to D_3 , resulting in an increase in the equilibrium price from P_1 to P_3 and an increase in the equilibrium quantity from Q_1 to Q_3 . A decrease in the price of a substitute would have the opposite effect, resulting in a decrease in demand for smart shirts. The demand curve would shift to the left, from D_1 to D_2 , resulting in a decrease in the equilibrium price from P_1 to P_2 and a decrease in the equilibrium quantity from Q_1 to Q_2 .

Thinking Critically

1. Suppose a technological change allows firms to lower the cost of producing smart shirts. Explain if this change will affect the demand curve for smart shirts. How would this change affect the market for smartwatches?
2. In 2014, smartwatch producers had difficulty filling the orders they received. Draw a demand and supply graph to illustrate this situation. All else equal, what would you expect to happen in this market if this situation persisted into the future, and how would this affect the market for complementary products like the smart shirt?

An increase in demand for smart shirts shifts the demand curve to the right. All else equal, equilibrium price and equilibrium quantity both increase. A decrease in demand has the opposite effect.

Economics in Your Life

After the chapter-opening real-world business case, we have added a personal dimension to the chapter opener with a feature titled *Economics in Your Life*, which asks students to consider how economics affects their lives. The feature piques the interest of students and emphasizes the connection between the material they are learning and their experiences.

Economics in Your Life

Will You Buy a Smartphone or a Smartwatch?

At the beginning of this chapter, we asked you to consider how you might choose between buying a smartwatch and buying a smartphone. There are certain activities, such as watching YouTube or Netflix, that you can do on a smartphone but not on a smartwatch. There are other activities, such as tracking calories burned during a workout, that are probably easier to do on a smartwatch. If you can engage in the activities you like most on either device, then you probably consider the two devices to be close substitutes, and you are likely to buy the one with the lower price. Suppose that you are currently leaning toward buying a smartphone because its price is lower than the price of a comparable smartwatch. If an increase in your income would cause you to change your decision and buy the smartwatch, then the smartphone is an inferior good for you.

The following are examples of the topics we cover in the *Economics in Your Life* feature:

- Will you buy a smartphone or a smartwatch? (Chapter 3, “Where Prices Come From: The Interaction of Demand and Supply”)
- Is your take-home pay affected by what your employer spends on your health insurance? (Chapter 7, “The Economics of Health Care”)
- Is an employer likely to cut your pay during a recession? (Chapter 24, “Aggregate Demand and Aggregate Supply Analysis”)

Solved Problems

Many students have great difficulty handling applied economics problems. We help students overcome this hurdle by including in each chapter two or three worked-out problems tied to select chapter-opening learning objectives. Our goals are to keep students focused on the main ideas of each chapter and give them a model of how to solve an economic problem by breaking it down step by step. Additional exercises in the end-of-chapter *Problems and Applications* section are tied to every *Solved Problem*.

Can We Predict Changes in the Price and Quantity of Beef?

Whether you like to eat hamburger or roast beef, the source of the meat is a rancher who raises cattle. A news story discussed how years of drought had raised the cost to ranchers of raising cattle. At the same time, consumer tastes have been changing, leading to a decline in the demand for beef. The demand and supply graphs to illustrate your answers to the following questions:

- Can we use this information to be certain whether the equilibrium quantity of beef will increase or decrease?
- Can we use this information to be certain whether the equilibrium price of beef will increase or decrease?

Solving the Problem

Step 1: Review the chapter material. This problem is about how shifts in demand and supply curves affect the equilibrium price, so you may want to review the section “The Effect of Shifts in Demand and Supply over Time,” which begins on page 90.

Step 2: Answer part (a) using demand and supply analysis. You are given the information that consumer tastes have changed, leading to a decline in demand for beef. So, the demand curve for beef has shifted to the left. You are also given the information that the cost of raising beef has increased. So, the supply curve for beef has also shifted to the left. The following graph shows both these shifts:

As Table 3.3 on page 92 summarizes, if the demand curve and the supply curve both shift to the left, the equilibrium quantity must decrease. Therefore, we can answer part (a) by stating that we are certain that the equilibrium quantity of beef will decrease.

Step 3: Answer part (b) using demand and supply analysis. The graph we drew in step 2 shows the equilibrium price of beef increasing. But given the information provided, the following graph would also be correct:

Unlike the graph in step 2, which shows the equilibrium price increasing, this graph shows the equilibrium price decreasing. The uncertainty about whether the equilibrium price will increase or decrease is consistent with what Table 3.3 shows happens when the demand curve and the supply curve both shift to the left. Therefore, the answer to part (b) is that we cannot be certain whether the equilibrium price of beef will increase or decrease.

Extra Credit: During 2013 and 2014, the equilibrium quantity of beef decreased while the equilibrium price of beef increased. We can conclude that both the decrease in demand for beef and the decrease in the supply of beef contributed to the decline in beef consumption. That the price of beef rose indicates that the decrease in supply had a larger effect on equilibrium in the beef market than did the decrease in demand.

Your Turn: For more practice, do related problems 4.7 and 4.8 on page 104 at the end of this chapter.

Don't Let This Happen to You

Remember: A Change in a Good's Price Does *Not* Cause the Demand or Supply Curve to Shift

Suppose a student is asked to draw a demand and supply graph to illustrate how an increase in the price of oranges would affect the market for apples, with other variables being constant. He draws the graph on the left and explains it as follows: “Because apples and oranges are substitutes, an increase in the price of oranges will cause an initial shift to the right in the demand curve for apples, from D_1 to D_2 . However, because this initial shift in the demand curve for apples results in a higher price for apples, P_2 , consumers will find apples less desirable, and the demand curve will shift to the left, from D_2 to D_3 , resulting in a final equilibrium price of P_3 .” Do you agree or disagree with the student's analysis? MyEconLab Study Plan

You should disagree. The student has correctly understood that an increase in the price of oranges will cause the demand curve for apples to shift to the right. But, the second demand curve shift the student describes,

from D_2 to D_3 , will not take place. Changes in the price of a product do not result in shifts in the product's demand curve. Changes in the price of a product result only in movements along a demand curve.

The graph on the right shows the correct analysis. The increase in the price of oranges causes the demand curve for apples to increase from D_1 to D_2 . At the original price, P_1 , the increase in demand initially results in a shortage of apples equal to $Q_3 - Q_1$. But, as we have seen, a shortage causes the price to increase until the shortage is eliminated. In this case, the price will rise to P_2 , where both the quantity demanded and the quantity supplied are equal to Q_2 . Notice that the increase in price causes a decrease in the quantity demanded, from Q_3 to Q_2 , but does *not* cause a decrease in demand.

Your Turn: Test your understanding by doing related problems 4.13 and 4.14 on page 163 at the end of this chapter.

Don't Let This Happen to You

We know from many years of teaching which concepts students find most difficult. Each chapter contains a box feature called *Don't Let This Happen to You* that alerts students to the most common pitfalls in that chapter's material. We follow up with a related question in the end-of-chapter *Problems and Applications* section.

Making the Connection

Each chapter includes two to four *Making the Connection* features that provide real-world reinforcement of key concepts and help students learn how to interpret what they read on the Web and in newspapers. Most *Making the Connection* features use relevant, stimulating, and provocative news stories focused on businesses and policy issues. One-third of them are new to this edition, and most others have been updated. Several discuss health care, which remains a pressing policy issue. Each *Making the Connection* has at least one supporting end-of-chapter problem to allow students to test their understanding of the topic discussed.

Are Smartwatches Substitutes for Smartphones?

Two products are rarely perfect substitutes because consumers may find them more or less useful for some purposes. As Apple and other firms began selling smartwatches, a key question they needed to answer was whether consumers considered smartwatches close substitutes for smartphones. You can use either a smartwatch or a smartphone to check the time, send a text, keep a list of appointments, or use a GPS map. But you need a smartphone if you want to surf the Web or watch a movie, while you are better off buying a smartwatch if you want to monitor your heartbeat or keep track of how many calories you are burning while exercising.

Is the smartwatch a hot new must-have gadget, even for people who already own a smartphone?

So smartwatches and smartphones are substitutes—but they aren't perfect substitutes. To correctly forecast sales and produce the correct quantity of smartwatches, firms that sell them need to evaluate how close substitutes consumers consider smartwatches and smartphones to be. Many people who might consider buying a smartwatch already own a smartphone. So the closer consumers consider the two products to be as substitutes, the less likely they are to buy a smartwatch in addition to a smartphone.

When Apple introduced the Apple Watch in 2015, sales were initially very strong, which would seem to indicate that many consumers believed that the unique features of the smartwatch made it worth buying, even if they owned a smartphone. Some analysts, though, wondered how large future sales would be after people who buy each new electronic device soon after it hits the market—early adopters—had made their purchases. One early reviewer of the Apple Watch noted that he was unsure “that I need this thing on my wrist every day.” Similarly, the *Economist* magazine offered the opinion, “Apple seems unlikely to turn its watch into the next big must-have gadget. ... People are unlikely to want to shell out ... \$350 ... for something with so few extra functions.”

Other industry observers were more optimistic about the size of the market for smartwatches. Writing in the *Wall Street Journal*, one analyst argued that smartwatches performed several functions faster or more conveniently than smartphones. He concluded, “Billions of consumers who own a smartphone are likely to consider purchasing a smartwatch.” Given these different evaluations, it wasn't surprising that forecasts of sales of the Apple Watch during its first year varied widely from 8 million to 41 million.

In the end, as with most new products, the success of smartwatches depends on whether consumers see them as filling a need that other products don't meet. In other words, the less close a substitute consumers believe smartwatches to be for smartphones, the more likely they are to buy a smartwatch.

MyEconLab Study Plan

Graphs and Summary Tables

Graphs are an indispensable part of a principles of economics course but are a major stumbling block for many students. Every chapter except Chapter 1 includes end-of-chapter problems that require students to draw, read, and interpret graphs. Interactive graphing exercises appear on the book's supporting Web site. We use four devices to help students read and interpret graphs:

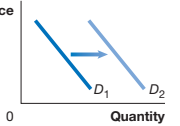

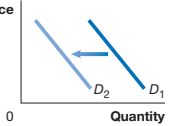

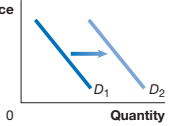

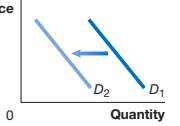

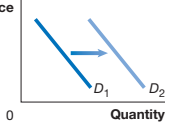

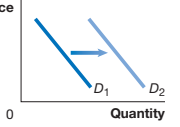

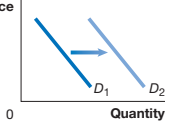

1. Detailed captions
2. Boxed notes
3. Color-coded curves
4. Summary tables with graphs (see pages 138, 143, and 888 for examples)

MyEconLab Animation

Figure 3.3
A Change in Demand versus a Change in Quantity Demanded

If the price of smartwatches falls from \$450 to \$400, the result will be a movement along the demand curve from point A to point B—an increase in quantity demanded from 3 million to 4 million. If consumers' incomes increase, or if another factor changes that makes consumers want more of the product at every price, the demand curve will shift to the right—an increase in demand. In this case, the increase in demand from D_1 to D_2 causes the quantity of smartwatches demanded at a price of \$450 to increase from 3 million at point A to 5 million at point C.

Table 3.1 Variables That Shift Market Demand Curves	An increase in ...	shifts the demand curve ...	because ...

Review Questions and Problems and Applications—Grouped by Learning Objective to Improve Assessment

All end-of-chapter material—*Summary*, *Review Questions*, and *Problems and Applications*—is grouped under learning objectives. The goals of this organization are to make it easier for instructors to assign problems based on learning objectives, both in the book and in MyEconLab, and to help students efficiently review material that they find difficult. If students have difficulty with a particular learning objective, an instructor can easily identify which end-of-chapter questions and problems support that objective and assign them as homework or discuss them in class. Every exercise in a chapter's *Problems and Applications* section is available in MyEconLab. Using MyEconLab, students can complete these and many other exercises online, get tutorial help, and receive instant feedback and assistance on exercises they answer incorrectly. Also, student learning will be enhanced by having the summary material and problems grouped together by learning objective, which will allow them to focus on the parts of the chapter they find most challenging. Each major section of the chapter, paired with a learning objective, has at least two review questions and three problems.

As in the previous editions, we include one or more end-of-chapter problems that test students' understanding of the content presented in the *Solved Problem*, *Making the Connection*, and *Don't Let This Happen to You* special features in the chapter. Instructors can cover a

feature in class and assign the corresponding problem for homework. The Test Item Files also include test questions that pertain to these special features.

Real-Time Data Exercises

Select chapters end with at least two *Real-Time Data Exercises* that help students become familiar with a key data source, learn how to locate data, and develop skills in interpreting data. *Real-Time Data Analysis (RTDA) Exercises*, marked with , allow students and instructors to use the very latest data from FRED.

Integrated Supplements

The authors and Pearson Education/Prentice Hall have worked together to integrate the text, print, and media resources to make teaching and learning easier.

MyEconLab

MyEconLab is a unique online course management, testing, and tutorial resource.

For the Instructor

Instructors can choose how much or how little time to spend setting up and using MyEconLab. Here is a snapshot of what instructors are saying about MyEconLab:

MyEconLab offers [students] a way to practice every week. They receive immediate feedback and a feeling of personal attention. As a result, my teaching has become more targeted and efficient.—Kelly Blanchard, Purdue University

Students tell me that offering them MyEconLab is almost like offering them individual tutors.—Jefferson Edwards, Cypress Fairbanks College

MyEconLab's eText is great—particularly in that it helps offset the skyrocketing cost of textbooks. Naturally, students love that.—Doug Gehrke, Moraine Valley Community College

Each chapter contains two preloaded exercise sets that can be used to build an individualized study plan for each student. These study plan exercises contain tutorial resources, including instant feedback, links to the appropriate learning objective in the eText, pop-up definitions from the text, and step-by-step guided solutions, where appropriate. After the initial setup of the course by the instructor, student use of these materials requires no further instructor setup. The online grade book records each student's performance and time spent on the tests and study plan and generates reports by student or chapter.

Alternatively, instructors can fully customize MyEconLab to match their course exactly, including reading assignments, homework assignments, video assignments, current news assignments, and quizzes and tests. Assignable resources include:

- Preloaded exercise assignments sets for each chapter include the student tutorial resources mentioned earlier.
- Preloaded quizzes for each chapter are unique to the text and not repeated in the study plan or homework exercise sets.
- Study plan problems are similar to the end-of-chapter problems and numbered exactly as in the book to make assigning homework easier.
- *Real-Time Data Analysis Exercises*, marked with , allow students and instructors to use the very latest data from FRED. By completing the exercises, students become familiar

with a key data source, learn how to locate data, and develop skills in interpreting data. In the eText available in MyEconLab, select figures labeled MyEconLab Real-Time Data allow students to display a pop-up graph updated with real-time data from FRED.

- *Current News Exercises* provide a turnkey way to assign gradable news-based exercises in MyEconLab. Each week, Pearson scours the news, finds a current microeconomics article and a current macroeconomics article, creates exercises around these news articles, and adds them to MyEconLab. Assigning and grading current news-based exercises that deal with the latest micro and macro events and policy issues has never been more convenient.
- *Experiments in MyEconLab* provide a fun and engaging way to promote active learning and mastery of important economic concepts. Pearson's Experiments program is flexible, easy-to-assign, auto-graded, and available in Single and Multiplayer versions. Single-player experiments allow your students to play against virtual players from anywhere at any time, as long as they have an Internet connection. Multiplayer experiments allow you to assign and manage a real-time experiment with your class. Pre- and post-questions for each experiment are available for assignment in MyEconLab. For a complete list of available experiments, visit www.myeconlab.com.
- Test Item File questions allow you to assign quizzes or homework that look just like your exams.
- *Econ Exercise Builder* allows you to build customized exercises. Exercises include multiple-choice, graph drawing, and free-response items, many of which are generated algorithmically so that each time a student works them, a different variation is presented. MyEconLab grades every problem type except essays—even problems with graphs. When working homework exercises, students receive immediate feedback, with links to additional learning tools.

Customization and Communication

MyEconLab in MyLab/Mastering provides additional optional customization and communication tools. Instructors who teach distance-learning courses or very large lecture sections find the MyLab/Mastering format useful because they can upload course documents and assignments, customize the order of chapters, and use communication features such as Document Sharing, Chat, ClassLive, and Discussion Board.

For the Student

MyEconLab puts students in control of their learning through a collection of testing, practice, and study tools tied to the online, interactive version of the textbook and other media resources. Here is a snapshot of what students are saying about MyEconLab:

It was very useful because it had EVERYTHING, from practice exams to exercises to reading. Very helpful.—student, Northern Illinois University

I would recommend taking the quizzes on MyEconLab because it gives you a true account of whether or not you understand the material.—student, Montana Tech

It made me look through the book to find answers, so I did more reading.—student, Northern Illinois University

Students can study on their own or can complete assignments created by their instructor. In MyEconLab's structured environment, students practice what they learn, test their understanding, and pursue a personalized study plan generated from their performance on sample tests and from quizzes created by their instructors. In Homework or Study Plan mode, students have access to a wealth of tutorial features, including:

- Instant feedback on exercises that helps students understand and apply the concepts
- Links to the eText to promote reading of the text just when the student needs to revisit a concept or an explanation

- Step-by-step guided solutions that force students to break down a problem in much the same way an instructor would do during office hours
- Pop-up key term definitions from the eText to help students master the vocabulary of economics
- A graphing tool that is integrated into the various exercises to enable students to build and manipulate graphs to better understand how concepts, numbers, and graphs connect

Additional MyEconLab Tools

MyEconLab includes the following additional features:

- **Pearson eText.** Students actively read and learn, and with more engagement than ever before, through embedded and auto-graded practice, real-time data-graph updates, animations, author videos, and more.
- **Glossary flashcards.** Every key term is available as a flashcard, allowing students to quiz themselves on vocabulary from one or more chapters at a time.

MyEconLab content has been created through the efforts of Chris Annala, State University of New York–Geneseo; Charles Baum, Middle Tennessee State University; Peggy Dalton, Frostburg State University; Carol Dole, Jacksonville University; David Foti, Lone Star College; Sarah Ghosh, University of Scranton; Satyajit Ghosh, University of Scranton; Melissa Honig, Pearson Education; Woo Jung, University of Colorado; Courtney Kamauf, Pearson Education; Chris Kauffman, University of Tennessee–Knoxville; Russell Kellogg, University of Colorado–Denver; Noel Lotz, Pearson Education; Katherine McCann, University of Delaware; Daniel Mizak, Frostburg State University; Christine Polek, University of Massachusetts–Boston; Mark Scanlan, Stephen F. Austin State University; Leonie L. Stone, State University of New York–Geneseo; and Bert G. Wheeler, Cedarville University.

Other Resources for the Instructor

Instructor's Manuals

Edward Scahill of the University of Scranton prepared the *Instructor's Manual* for *Microeconomics* and for *Macroeconomics*. The *Instructor's Manuals* include chapter-by-chapter summaries, learning objectives, extended examples and class exercises, teaching outlines incorporating key terms and definitions, teaching tips, topics for class discussion, new *Solved Problems*, new *Making the Connection* features, and solutions to all review questions, problems, and real-time data exercises in the book. The *Instructor's Manuals* are available in print and for download from the Instructor's Resource Center (www.pearsonglobaleditions.com/Hubbard). The solutions to the end-of-chapter review questions and problems were prepared by the authors and Edward Scahill of the University of Scranton.

Two Test Item Files

Randy Methenitis of Richland College prepared Test Item Files for *Microeconomics* and for *Macroeconomics*. Each Test Item File includes 4,000 multiple-choice, true/false, short-answer, and graphing questions. There are questions to support each key feature in the book. The Test Item Files are available in print and for download from the Instructor's Resource Center (www.pearsonglobaleditions.com/Hubbard). Test questions are annotated with the following information:

- **Difficulty**—1 for straight recall, 2 for some analysis, 3 for complex analysis
- **Type**—multiple-choice, true/false, short-answer, essay

- **Topic**—the term or concept the question supports
- **Learning outcome**
- **AACSB** (see the description that follows)
- **Page number** in the text
- **Special feature in the main book**—chapter-opening business example, *Economics in Your Life*, *Solved Problem*, *Making the Connection*, and *Don't Let This Happen to You*

The Association to Advance Collegiate Schools of Business (AACSB)

The Test Item File author has connected select questions to the general knowledge and skill guidelines found in the AACSB Assurance of Learning Standards.

What Is the AACSB?

The AACSB is a not-for-profit corporation of educational institutions, corporations, and other organizations devoted to the promotion and improvement of higher education in business administration and accounting. A collegiate institution offering degrees in business administration or accounting may volunteer for AACSB accreditation review. The AACSB makes initial accreditation decisions and conducts periodic reviews to promote continuous quality improvement in management education. Pearson Education is a proud member of the AACSB and is pleased to provide advice to help you apply AACSB Assurance of Learning Standards.

What Are AACSB Assurance of Learning Standards?

One of the criteria for AACSB accreditation is the quality of curricula. Although no specific courses are required, the AACSB expects a curriculum to include learning experiences in the following categories of Assurance of Learning Standards:

- Written and Oral Communication
- Ethical Understanding and Reasoning
- Analytical Thinking Skills
- Information Technology
- Diverse and Multicultural Work
- Reflective Thinking
- Application of Knowledge

Questions that test skills relevant to these standards are tagged with the appropriate standard. For example, a question testing the moral questions associated with externalities would receive the Ethical Understanding and Reasoning tag.

How Can Instructors Use the AACSB Tags?

Tagged questions help you measure whether students are grasping the course content that aligns with the AACSB guidelines noted earlier. This in turn may suggest enrichment activities or other educational experiences to help students achieve these skills.

TestGen

The computerized TestGen package allows instructors to customize, save, and generate classroom tests. The test program permits instructors to edit, add, or delete questions from the Test Item Files; analyze test results; and organize a database of tests and student results. This software allows for extensive flexibility and ease of use. It provides many options for organizing and displaying tests, along with search and sort features. The software and the Test Item Files can be downloaded from the Instructor's Resource Center (www.pearsonglobaleditions.com/Hubbard).

PowerPoint Lecture Presentation

Three sets of PowerPoint slides, prepared by Paul Holmes of Ashland University, are available:

1. A comprehensive set of PowerPoint slides can be used by instructors for class presentations or by students for lecture preview or review. These slides include all the graphs, tables, and equations in the textbook. Two versions are available—step-by-step mode, in which you can build graphs as you would on a blackboard, and automated mode, in which you use a single click per slide.
2. A comprehensive set of PowerPoint slides have Classroom Response Systems (CRS) questions built in. Instructors can download these PowerPoint presentations from the Instructor’s Resource Center (www.pearsonglobaleditions.com/Hubbard).
3. A student version of the PowerPoint slides is available as .pdf files. This version allows students to print the slides and bring them to class for note taking. Instructors can download these PowerPoint presentations from the Instructor’s Resource Center (www.pearsonglobaleditions.com/Hubbard).

Learning Catalytics

Learning Catalytics is a “bring your own device” Web-based student engagement, assessment, and classroom intelligence system. This system generates classroom discussion, guides lectures, and promotes peer-to-peer learning with real-time analytics. Students can use any device to interact in the classroom, engage with content, and even draw and share graphs.

To learn more, ask your local Pearson representative or visit www.learningcatalytics.com.

Digital Interactives

Focused on a single core topic and organized in progressive levels, each interactive immerses students in an assignable and auto-graded activity. Digital Interactives are also engaging lecture tools for traditional, online, and hybrid courses, many incorporating real-time data, data displays, and analysis tools for rich classroom discussions.

Other Resources for the Student

In addition to MyEconLab, Pearson provides the following resources.

Dynamic Study Modules

With a focus on key topics, these modules work by continuously assessing student performance and activity in real time and, using data and analytics, provide personalized content to reinforce concepts that target each student’s particular strengths and weaknesses.

PowerPoint Slides

For student use as a study aid or note-taking guide, PowerPoint slides, prepared by Paul Holmes of Ashland University, can be downloaded from MyEconLab or the Instructor’s Resource Center and made available to students. The slides include:

- All graphs, tables, and equations in the text
- Figures in step-by-step mode and automated modes, using a single click per graph curve
- End-of-chapter key terms with hyperlinks to relevant slides

Accuracy Review Board and Reviewers

The guidance and recommendations of the following instructors helped us develop the revision plans for the sixth edition and the supplements package. While we could not incorporate every suggestion from every consultant board member, reviewer, or accuracy checker, we do thank each and every one of you and acknowledge that your feedback was indispensable in developing this text. We greatly appreciate your assistance in making this the best text it could be; you have helped teach a whole new generation of students about the exciting world of economics.

Accuracy Review Board

Our accuracy checkers did a particularly painstaking and thorough job of helping us proof the graphs, equations, and features of the text and supplements. We are grateful for their time and commitment:

Fatma Abdel-Raouf, Goldey-Beacom College
 Clare Battista, California Polytechnic State University
 Doris Bennett, Jacksonville State University
 Harry Ellis, University of North Texas
 Robert Gillette, University of Kentucky
 Edward T. Gullason, formerly, Dowling College
 Anthony Gyapong, Pennsylvania State University—

 Randy Methenitis, Richland College
 Brian Rosario, University of California–Davis
 Edward Scahill, University of Scranton

Reviewers

The guidance and thoughtful recommendations of many instructors helped us develop and implement a revision plan that improved the book's content, enhanced the figures, and strengthened the assessment features. We extend special thanks to Edward Scahill of the University of Scranton for helping us revise the chapter openers and the solutions to the end-of-chapter questions and problems, to Randy Methenitis of Richland College for helping us revise the *An Inside Look* feature in Chapters 1–4, and to Fernando Quijano for creating all the figures in the book and supplements. We are grateful for the comments and many helpful suggestions received from the following reviewers:

A Word of Thanks

Once again, we benefited greatly from the dedication and professionalism of the Pearson Economics team. Executive Editor David Alexander's energy and support were indispensable. David helped mold the presentation and provided words of encouragement whenever our energy flagged. Executive Development Editor Lena Buonanno worked tirelessly to ensure that this text was as good as it could be and to coordinate the many moving parts involved in a project of this magnitude. This new edition posed particular challenges, and we remain astonished at the amount of time, energy, and unfailing good humor she brings to this project. As we worked on the first edition, former Director of Key Markets David Theisen provided invaluable insight into how best to structure a principles text. His advice helped shape nearly every chapter. Lindsey Sloan managed all aspects of the media resources and helped keep both them and the print book on schedule. Carla Thompson managed the entire production process, and Sarah Dumouchelle managed the extensive supplement package that accompanies the book. Carla Thompson and Jonathan Boylan turned our manuscript pages into a beautiful published book. Editorial Assistant Michelle Zeng assisted the team in completing several tasks to help produce both the media resources and the book. We received excellent research assistance on this and previous editions from Dante DeAntonio, Ed Timmons, Matthew Saboe, David Van Der Goes, and Jason Hockenberry. We thank Elisa Adams, Pam Smith, Elena Zeller, Jennifer Brailsford, Lindsay K. Clark, Deborah Crowell, Ellen Vandevort Wolf, and Cindy O'Brien for their careful proofreading of first- and second-round page proofs. Over all editions of our books, we received helpful feedback and recommendations from Lehigh University faculty colleagues Frank R. Gunter, Thomas J. Hyclak, and Robert J. Thornton.

As instructors, we recognize how important it is for students to view graphs that are clear and accessible. We are fortunate to have Fernando Quijano render all the figures in our books and also our supplements. Market feedback on the figures continues to be positive. We extend our thanks to Fernando not only for collaborating with us and creating the best figures possible but also for his patience with our demanding schedule.

This sixth edition has several media components, which required skilled and patient creators and developers. We extend special thanks to Andy Taylor of Hodja Media for preparing the video clips and to Paul Graf of the University of Indiana–Bloomington for preparing the graph animations. These videos and animations are an important part of our revision.

A good part of the burden of a project of this magnitude is borne by our families. We appreciate the patience, support, and encouragement of our wives and children.

CHAPTER 1

Economics: Foundations and Models

Chapter Outline and Learning Objectives

- 1.1 Three Key Economic Ideas**, page 62
Explain these three key economic ideas: People are rational; people respond to economic incentives; and optimal decisions are made at the margin.
- 1.2 The Economic Problem That Every Society Must Solve**, page 66
Discuss how an economy answers these questions: What goods and services will be produced? How will the goods and services be produced? Who will receive the goods and services produced?
- 1.3 Economic Models**, page 70
Describe the role of models in economic analysis.
- 1.4 Microeconomics and Macroeconomics**, page 75
Distinguish between microeconomics and macroeconomics.
- 1.5 A Preview of Important Economic Terms**, page 75
Define important economic terms.
- Appendix: Using Graphs and Formulas**, page 85
Use graphs and formulas to analyze economic situations.

Will Smart Devices Revolutionize Health Care?

If you get sick, your doctor may send you to a hospital or clinic for a series of tests. You'll need to schedule an appointment, travel to the clinic, and spend time in a waiting room. Depending on your medical insurance, you'll also need to pay for the tests. But what if you had an inexpensive smart device that would allow you to test yourself at home and send the results to your doctor? Walter De Brouwer is a Belgian-born entrepreneur who worked in various industries, including telecommunications and publishing. When his son was badly injured in a fall, De Brouwer was inspired to create such a smart device. His California-based firm, Scanadu, developed the Scout, a small disk that when pressed against the side of your head can record your blood pressure, heart rate, and temperature. According to the firm's advertising, the Scout allows you to "Check your health as easily as your e-mail." Some people have compared the Scout to the Tricorder medical device from the *Star Trek* TV series.

Scanadu is not alone in developing new consumer medical devices. The Apple Watch monitors your heart rate, as well as how much exercise you've performed and how many calories you've burned; OraSure sells a home HIV test; and Alivecor sells a device that can be attached to a smartphone and allows people with heart problems to perform their own electrocardiograms.

These firms are reacting to several trends: Many people have become more

health conscious; as the population ages, more people are experiencing medical problems; and technological progress has made it possible for small electronic devices, including smartwatches and smartphones, to monitor blood pressure and perform other tasks. These firms are responding to changing *economic incentives*. As we will see, the *market system* provides firms with the incentive and the resources to both create new goods and services and improve existing goods and services. The result is an ever-increasing standard of living for the average person.

Over time, as technology, consumer demand, and government policies change, the market system enables the flow of resources out of some industries and into others. For instance, in the United States resources have been flowing out of the production of manufactured goods such as steel, shoes, and furniture and into the production of services, including medical services. In fact, health care has been the most rapidly expanding sector of the U.S. economy.

AN INSIDE LOOK on **page 136** explores how Google is adding to its growing list of technological innovations by developing smart contact lenses to help patients manage diabetes.

Economics in Your Life

Will There Be Plenty of Jobs Available in the Health Care Industry?

The World Health Organization (WHO) reported the average physician density across the 28 European Union (EU) member states as 3.4 doctors per 1,000 population as at 2013. The European Commission (EC) forecasts a potential shortfall of 230,000 physicians and 1 million healthcare workers by 2020. The decreased number of new entrants would leave 13.8 percent of the health care industry across the EU uncovered. However, the EC projects 8 million jobs in the industry between 2010 and 2020, comprising one million new jobs and 7 million replacement jobs. The growth rate in this sector is projected to be 5 percent, above the EU average of 3 percent. What are the factors on which the EC bases these forecasts, and how reliable are these forecasts? As you read this chapter, try to answer this question. You can check your answer against the one we provide on **page 77** at the end of this chapter.

In this book, we use economics to answer questions such as the following:

- What determines the prices of smartwatches?
- Why have health care costs risen so rapidly?
- Why do firms engage in international trade, and how do government policies affect international trade?
- Why does the government control the prices of some goods and services, and what are the effects of those controls?

Economists do not always agree on the answers to every question, and there are lively debates on some issues. Because new problems and issues are constantly arising, economists are always developing new methods to analyze economic questions.

All the topics we discuss in this book illustrate a basic fact of life: To attain our goals, we must make choices. We must make choices because we live in a world of **scarcity**, which means that although our wants are *unlimited*, the resources available to fulfill those wants are *limited*. You might want to own a BMW and spend each summer vacationing at five-star European hotels, but unless Bill Gates is a close and generous relative, you probably lack the funds to fulfill these wants. Every day, you make choices as you spend your limited income on the many goods and services available. The finite amount of time you have also limits your ability to attain your goals. If you spend an hour studying for your economics midterm, you have one hour less to study for your history midterm. Firms and the government are in the same situation as you: They must also attain their goals with limited resources. **Economics** is the study of the choices consumers, business managers, and government officials make to attain their goals, given their scarce resources.

We begin this chapter by discussing three important economic ideas that we will return to many times in the following chapters: *People are rational*, *people respond to economic incentives*, and *optimal decisions are made at the margin*. Then, we consider the three fundamental questions that any economy must answer: *What goods and services will be produced?* *How will the goods and services be produced?* and *Who will receive the goods and services produced?* Next, we consider the role of *economic models* in analyzing economic issues. **Economic models** are simplified versions of reality used to analyze real-world economic situations. We will explore why economists use models and how they construct them. Finally, we will discuss the difference between microeconomics and macroeconomics, and we will preview some important economic terms.

Scarcity A situation in which unlimited wants exceed the limited resources available to fulfill those wants.

Economics The study of the choices people make to attain their goals, given their scarce resources.

Economic model A simplified version of reality used to analyze real-world economic situations.

Market A group of buyers and sellers of a good or service and the institution or arrangement by which they come together to trade.

1.1 Three Key Economic Ideas

LEARNING OBJECTIVE: Explain these three key economic ideas: *People are rational; people respond to economic incentives; and optimal decisions are made at the margin.*

Whether your goal is to buy a smartwatch or find a part-time job, you will interact with other people in *markets*. A **market** is a group of buyers and sellers of a good or service and the institution or arrangement by which they come together to trade. Examples of markets are the markets for smartwatches, houses, haircuts, stocks and bonds, and labor. Most of economics involves analyzing how people make choices and interact in markets. Here are the three important ideas about markets that we'll return to frequently:

1. People are rational.
2. People respond to economic incentives.
3. Optimal decisions are made at the margin.

People Are Rational

Economists generally assume that people are rational. This assumption does *not* mean that economists believe everyone knows everything or always makes the “best” decision. It means that economists assume that consumers and firms use all available information as they act to achieve their goals. Rational individuals weigh the benefits and costs of each action, and they choose an action only if the benefits outweigh the costs. For example, if Apple charges a price of \$349 for the basic model of its smartwatch, economists assume that the managers at Apple have estimated that this price will earn the company the most profit. Even though the managers may be wrong—maybe a price of \$325 or \$375 would be more profitable—economists assume that the managers at Apple have acted rationally, on the basis of the information available to them, in choosing the price of \$349. Although not everyone behaves rationally all the time, the assumption of rational behavior is very useful in explaining most of the choices that people make.

MyEconLab Concept Check

People Respond to Economic Incentives

Human beings act from a variety of motives, including envy, compassion, and religious belief. While not ignoring other motives, economists emphasize that consumers and firms consistently respond to *economic incentives*. This point may seem obvious, but it is often overlooked. For example, according to an article in the *Wall Street Journal*, the FBI couldn’t understand why banks were not taking steps to improve security in the face of an increase in robberies: “FBI officials suggest that banks place uniformed, armed guards outside their doors and install bullet-resistant plastic, known as a ‘bandit barrier,’ in front of teller windows.” FBI officials were surprised that few banks took their advice. But the article also reported that installing bullet-resistant plastic costs \$10,000 to \$20,000, and a well-trained security guard receives \$50,000 per year in salary and benefits. The average loss in a bank robbery is only about \$1,200. The economic incentive to banks is clear: It is less costly to put up with bank robberies than to take additional security measures. FBI agents may be surprised by how banks respond to the threat of robberies—but economists are not.

In each chapter, the *Making the Connection* feature discusses a news story or another application related to the chapter material. Read this *Making the Connection* for a discussion of whether people respond to economic incentives even when deciding how much to eat and how much to exercise.

Does Health Insurance Give People an Incentive to Become Obese?

Obesity is a significant health problem in the United States. Body mass index (BMI) is a measurement of a person’s weight relative to the person’s height. The U.S. Centers for Disease Control and Prevention (CDC) defines *obesity* for an adult as having a body mass index (BMI) of 30 or greater. For example, a 5'4" adult with a BMI of 30 is 30 pounds overweight. Obesity is a factor in a variety of diseases, including heart disease, stroke, diabetes, and hypertension.

The two maps on the next page show the dramatic increase in obesity between 1994 and 2013. In 1994, in a majority of states, only between 10 percent and 14 percent of the adult population was obese, and in no state was more than 20 percent of the adult population obese. By 2013, in every state, at least 20 percent of the adult population was obese, and in 43 states, at least 25 percent of the adult population was obese.

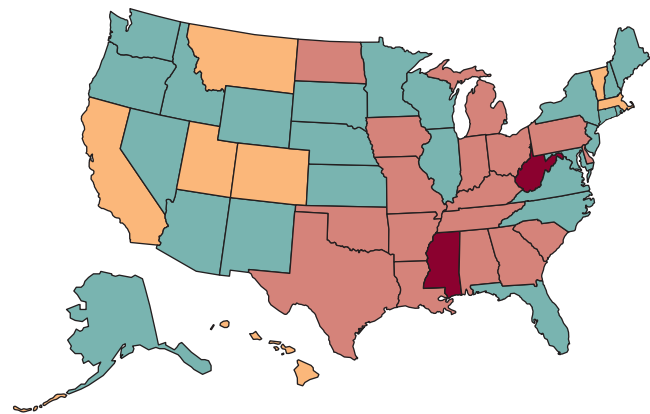

Many people who suffer from obesity have underlying medical conditions. For these people, obesity is a medical problem that they cannot control. The fact that obesity has increased, though, indicates that for some people obesity is the result of

diet and lifestyle choices. Potential explanations for the increase in obesity include greater intake of high-calorie fast foods, insufficient exercise, and a decline in the physical activity associated with many jobs. The CDC recommends that teenagers get a minimum of 60 minutes of aerobic exercise per day, a standard that only 15 percent of high school students meet. In 1960, 50 percent of jobs in the United States required at least moderate physical activity. Today, only 20 percent of jobs do. As a result, a typical worker today who may work at a computer is burning off about 130 fewer calories per workday than a worker in the 1960s who may have walked frequently in a manufacturing plant.

In addition to eating too much and not exercising enough, could having health insurance be a cause of obesity? Obese people tend to suffer more medical problems and so incur higher medical costs. Obese people with health insurance that will reimburse them for only part of their medical bills, or who have no health insurance, must pay some or all of these higher medical bills themselves. People with health insurance that covers most of their medical bills will not suffer as large a monetary cost from being obese. In other words, by reducing some of the costs of obesity, health insurance may give people an economic incentive to gain weight.

At first glance, this argument may seem implausible. Some people suffer from medical conditions that can make physical activity difficult or that can cause weight gain even with moderate eating, so they may become obese whether they have health insurance or not. Some people are obese because of poor eating habits or lack of exercise, and they probably don't consider health insurance when deciding whether to have another slice of chocolate cake or to watch Netflix instead of going to the gym. But if economists are correct about the importance of economic incentives, then we would expect that if we hold all other personal characteristics—such as age, gender, and income—constant, people with health insurance will be more likely to be overweight than people without health insurance.

Jay Bhattacharya and Kate Bundorf of Stanford University, Noemi Pace of the University of Venice, and Neeraj Sood of the University of Southern California, have analyzed the effects of health insurance on weight. Using a sample that followed nearly 80,000 people from 1989 to 2004, they found that after controlling for factors including age, gender, income, education, and race, people with health insurance were significantly more likely to be overweight than people without health insurance. Having private health insurance increased BMI by 1.3 points. Having public health insurance, such as Medicaid, which is a program under which the government provides health care to low-income people, increased BMI by 2.3 points. These findings suggest that

people respond to economic incentives even when making decisions about what they eat and how much they exercise.

Note: The exact formula for the body mass index is $BMI = (\text{Weight in pounds}/\text{Height in inches}^2) \times 703$.

Optimal Decisions Are Made at the Margin

Some decisions are “all or nothing.” For instance, when an entrepreneur decides whether to open a new restaurant, she starts the new restaurant or she doesn’t. When you decide whether to attend graduate school, you either enter graduate school or you don’t. But rather than being all or nothing, most decisions in life involve doing a little more or a little less. If you are trying to decrease your spending and increase your saving, the decision is not really between saving all the money you earn or spending it all. Rather, many small choices are involved, such as whether to buy a caffè mocha at Starbucks every day or just once a week.

Economists use the word *marginal* to mean “extra” or “additional.” Should you watch another hour of television or spend that hour studying? The *marginal benefit* (MB) of watching more television is the additional enjoyment you receive. The *marginal cost* (MC) is the reduction in your test score from having studied a little less. Should Apple produce an additional 300,000 smartwatches? Firms receive *revenue* from selling goods. Apple’s marginal benefit is the additional revenue it receives from selling 300,000 more smartwatches. Apple’s marginal cost is the additional cost—for wages, parts, and so forth—of producing 300,000 more smartwatches. *Economists reason that the optimal decision is to continue any activity up to the point where the marginal benefit equals the marginal cost—that is, to the point where MB = MC.* Often we apply this rule without consciously thinking about it. Usually you will know whether the additional enjoyment from watching a television program is worth the additional cost you pay by not spending that hour studying, without giving the decision a lot of thought. In business situations, however, firms often have to make careful calculations to determine, for example, whether the additional revenue received from increasing production is greater or less than the additional cost of the production. Economists refer to analysis that involves comparing marginal benefits and marginal costs as **marginal analysis**.

OraSure Makes a Decision at the Margin

OraSure is a medical technology firm based in Pennsylvania that produces, among other products, a device that allows consumers to test for HIV (human immunodeficiency virus) at home. In 2015, OraSure decided to reduce advertising for this device. The firm’s chief executive officer (CEO) stated that the advertising had not been as effective as he had hoped in increasing sales of the device. A news

story quoted him as saying, “Consequently, we had to adjust our [spending on advertising to] make it more proportional to revenue.” Assuming that reducing advertising will reduce OraSure’s sales of the device, how should the firm determine by what amount to reduce its advertising? Is it possible that OraSure is making a mistake by reducing its advertising? Briefly explain.

Solving the Problem

- Step 1: Review the chapter material.** This problem is about making decisions, so you may want to review the section “Optimal Decisions Are Made at the Margin,” which begins on page 65.
- Step 2: Explain how OraSure should determine by what amount to reduce its advertising.** We have seen that any activity should be continued to the point where the marginal benefit is equal to the marginal cost. In this case, OraSure apparently believes it is violating this rule because the additional cost from advertising is greater than the additional revenue it receives from the increased sales that result from the advertising. Therefore, OraSure will be better off reducing its advertising because the decline in cost will be greater than the decline in revenue. The company’s goal should be to reduce advertising spending to the amount where the additional revenue resulting from the last dollar of advertising equals the additional cost of the advertising.
- Step 3: Explain whether it is possible that OraSure’s decision to reduce advertising is a mistake.** OraSure’s CEO was disappointed in the extent to which advertising was increasing sales of the device. But the firm might still be spending the optimal amount on advertising even though the CEO hoped the effect of the advertising would be greater than it was. If the marginal revenue from the last dollar of advertising were equal to its marginal cost, reducing advertising spending would make the firm worse off. The only way to ensure a correct decision is for the firm to analyze the effect of changes in advertising spending on the firm’s revenues and costs.

1.2 The Economic Problem That Every Society Must Solve

LEARNING OBJECTIVE: Discuss how an economy answers these questions: What goods and services will be produced? How will the goods and services be produced? Who will receive the goods and services produced?

Because we live in a world of scarcity, any society faces the *economic problem* that it has only a limited amount of economic resources—such as workers, machines, and raw materials—and so can produce only a limited amount of goods and services. Therefore, every society faces **trade-offs**: Producing more of one good or service means producing less of another good or service. The best measure of the cost of producing a good or service is the value of what has to be given up to produce it. The **opportunity cost** of any activity—such as producing a good or service—is the highest-valued alternative that must be given up to engage in that activity. The concept of opportunity cost is very important in economics and applies to individuals, firms, and society as a whole. For instance, suppose that you earn a salary of \$100,000 per year working for Scanadu, the medical technology firm discussed at the beginning of the chapter. You decide to open your own firm to create and sell medical devices. In this case, the opportunity cost of the services you supply to your own firm is the \$100,000 you give up by not working for Scanadu, *even if you do not explicitly pay yourself a salary*. As in this example, opportunity costs often do not involve actual payments of money.

Trade-off The idea that, because of scarcity, producing more of one good or service means producing less of another good or service.

Opportunity cost The highest-valued alternative that must be given up to engage in an activity.

It's Saturday Afternoon; Why Aren't You at the Game?

For many students, attending college football games is an enjoyable way to spend

Saturday afternoons in the fall. However, some colleges have experienced a decline in the number of students attending their games. In 2014, average attendance at the 127 larger schools that make up the Football Bowl Subdivision declined to the lowest level in 14 years. In the past few years, nearly 40 percent of the tickets allocated to students at the University of Georgia have gone unsold. Even coach Nick Saban, whose University of Alabama team has won several national championships in recent years, has publically voiced concern about low student attendance at the team's games.

What explains the decrease in the number of students willing to attend football games? In some schools, rising ticket prices help explain the decline. One student at the University of Michigan was quoted as saying: "People are looking to trim costs, and for a lot of folks, football is an easy thing to cut. It's not essential to going to college."

Remember that the opportunity cost of engaging in an activity is the value of the best alternative that must be given up to engage in that activity. The opportunity cost of attending a college football game is *not* just the price of a ticket. If the price of a ticket to a game is \$50, your opportunity cost is the ticket price *plus* the value you place on what else you could do if you don't attend the game. At one time, relatively few college football games were televised, but today multiple cable networks broadcast games. If you attend your college's games, you miss the opportunity to watch the games being broadcast at the same time—in high-definition with replays shown from multiple camera angles and expert commentary to clarify what is happening. When watching games in your room or at a sports restaurant, you can also post to Facebook, Instagram, or Twitter, read e-mail, surf the Web, and take or receive phone calls. Wi-Fi and cellular reception is often poor in college stadiums, making these activities difficult.

So the opportunity cost of attending college football games has increased in recent years, not just because ticket prices have risen but because the number of alternative activities that students value highly has also increased. We expect that when the opportunity cost of engaging in an activity increases, people will engage in that activity less, as we've seen with student attendance at college football games.

Colleges have responded to declining student attendance by reducing ticket prices, improving Wi-Fi and cellular service, and installing high-definition video boards that show replays as they appear on television. Whether these attempts to lower the opportunity cost of attending college football games will succeed remains to be seen.

There are more empty seats at college football stadiums because the opportunity cost of attending games has increased.

Trade-offs force society to make choices when answering the following three fundamental questions:

1. *What* goods and services will be produced?
2. *How* will the goods and services be produced?
3. *Who* will receive the goods and services produced?

Throughout this book, we will return to these questions many times. For now, we briefly introduce each question.

What Goods and Services Will Be Produced?

How will society decide whether to produce more economics textbooks or more Blu-ray players? More daycare facilities or more football stadiums? Of course, “society” does not make decisions; only individuals make decisions. The answer to the question of what will be produced is determined by the choices that consumers and people working for firms or the government make. Every day, you help decide which goods and services firms will produce when you choose to buy an iPhone instead of a Samsung Galaxy or a caffè mocha rather than a chai tea. Similarly, managers at Apple must choose whether to devote the company’s scarce resources to making more iPhones or more smartwatches. Members of Congress and the president must choose whether to spend more of the federal government’s limited budget on breast cancer research or on repairing highways. In each case, consumers, managers of firms, and government policymakers face the problem of scarcity by trading off one good or service for another. And each choice made comes with an opportunity cost, measured by the value of the best alternative given up.

[MyEconLab](#) [Concept Check](#)

How Will the Goods and Services Be Produced?

Firms choose how to produce the goods and services they sell. In many cases, firms face a trade-off between using more workers or using more machines. For example, a local service station has to choose whether to provide car repair services using more diagnostic computers and fewer auto mechanics or fewer diagnostic computers and more auto mechanics. Similarly, movie studios have to choose whether to produce animated films using highly skilled animators to draw them by hand or fewer animators and more computers. In deciding whether to move production offshore to China, firms may need to choose between a production method in the United States that uses fewer workers and more machines and a production method in China that uses more workers and fewer machines.

[MyEconLab](#) [Concept Check](#)

Who Will Receive the Goods and Services Produced?

In the United States, who receives the goods and services produced depends largely on how income is distributed. The higher a person’s income, the more goods and services he or she can buy. Often, people are willing to give up some of their income—and, therefore, some of their ability to purchase goods and services—by donating to charities to increase the incomes of poorer people. Each year, Americans donate more than \$325 billion to charity, or an average donation of \$2,800 for each household in the country. An important policy question, however, is whether the government should intervene to make the distribution of income more equal. Such intervention already occurs in the United States because people with higher incomes pay a larger fraction of their incomes in taxes and because the government makes payments to people with low incomes. There is disagreement over whether the current attempts to redistribute income are sufficient or whether there should be more or less redistribution.

Centrally Planned Economies versus Market Economies

To answer the three questions—what, how, and who—societies organize their economies in two main ways. A society can have a **centrally planned economy** in which the government decides how economic resources will be allocated. Or a society can have a **market economy** in which the decisions of households and firms interacting in markets allocate economic resources.

From 1917 to 1991, the most important centrally planned economy in the world was that of the Soviet Union, which was established when Vladimir Lenin and the Communist Party staged a revolution and took control of the Russian Empire. In the Soviet Union, the government decided what goods to produce, how the goods would be produced, and who would receive the goods. Government employees managed factories and stores. The objective of these managers was to follow the government’s orders rather than to satisfy the wants of consumers.

Centrally planned economy An economy in which the government decides how economic resources will be allocated.

Market economy An economy in which the decisions of households and firms interacting in markets allocate economic resources.

Centrally planned economies like that of the Soviet Union have not been successful in producing low-cost, high-quality goods and services. As a result, the standard of living of the average person in a centrally planned economy tends to be low. All centrally planned economies have also been political dictatorships. Dissatisfaction with low living standards and political repression finally led to the collapse of the Soviet Union in 1991. Today, only North Korea still has a completely centrally planned economy.

All high-income democracies, including the United States, Canada, Japan, and the countries of Western Europe, have market economies. Market economies rely primarily on privately owned firms to produce goods and services and to decide how to produce them. Markets, rather than the government, determine who receives the goods and services produced. In a market economy, firms must produce goods and services that meet the wants of consumers, or the firms will go out of business. In that sense, it is ultimately consumers who decide what goods and services will be produced. Because firms in a market economy compete to offer the highest-quality products at the lowest price, they are under pressure to use the lowest-cost methods of production. For example, in the past 10 years, some U.S. firms have been under pressure to reduce their costs to meet competition from Chinese firms.

In a market economy, the income of an individual is determined by the payments he receives for what he has to sell. If you become a civil engineer, and firms are willing to pay a salary of \$85,000 per year for someone with your training and skills, you will have this amount of income to purchase goods and services. If you also buy a house that you rent out, your income will be even higher. One of the attractive features of markets is that they reward hard work. Generally, the more extensive the training you have received and the longer the hours you work, the higher your income will be. Of course, luck—both good and bad—also plays a role here. Someone might have a high income because she won the state lottery, while someone else might have a low income because he has severe medical problems. We can conclude that market economies respond to the question, “Who receives the goods and services produced?” with the answer, “Those who are most willing and able to buy them.” MyEconLab Concept Check

The Modern “Mixed” Economy

After the Industrial Revolution and the ensuing rise of private enterprises in the 1700s and 1800s, the European governments’ intervention in the regulation of product markets was minimal. However, the public sector was essential for the provision of basic public goods. In the 1920s, with the ongoing First World War (WWI), significant economic problems persisted throughout Europe, and the continent stagnated until it was overwhelmed by the Great Depression. The effects of the U.S. stock market crash of 1929 and the subsequent meltdown of the U.S. economy were soon felt throughout Europe, raising European unemployment and business bankruptcy to unprecedented levels. This is when governments realized the need to heavily intervene by increasing public expenditure and introducing government-mandated social benefits. After the devastating impact of the Second World War (WWII), Europeans demanded that their governments regulate wages and establish social security networks against unemployment, illness, retirement, and disability. They also required better medical and educational services in order to attain equitable income, social mobility, and higher living standards.

Some economists argue that the extent of government intervention makes it no longer accurate to refer to the economies of the United States, Canada, Japan, and Western Europe as pure market economies. Instead, they should be referred to as *mixed economies*. A **mixed economy** is still primarily a market economy because most economic decisions result from the interaction of buyers and sellers in markets. However, the government plays a significant role in the allocation of resources. As we will see in later chapters, economists continue to debate the role government should play in a market economy.

One of the most important developments in the international economy in recent years has been the movement of China from being a centrally planned economy to being a more mixed economy. The Chinese economy suffered decades of economic

Mixed economy An economy in which most economic decisions result from the interaction of buyers and sellers in markets but in which the government plays a significant role in the allocation of resources.

stagnation following the takeover of the government in 1949 by Mao Zedong and the Communist Party. Although China remains a political dictatorship, the production of most goods and services is now determined in the market rather than by the government. The result has been rapid economic growth that has lifted more than a billion people in China out of poverty.

MyEconLab Concept Check

Productive efficiency A situation in which a good or service is produced at the lowest possible cost.

Allocative efficiency A state of the economy in which production is in accordance with consumer preferences; in particular, every good or service is produced up to the point where the last unit provides a marginal benefit to society equal to the marginal cost of producing it.

Voluntary exchange A situation that occurs in markets when both the buyer and the seller of a product are made better off by the transaction.

Equity The fair distribution of economic benefits.

Efficiency and Equity

Market economies tend to be more efficient than centrally planned economies. There are two types of efficiency. **Productive efficiency** occurs when a good or service is produced at the lowest possible cost. **Allocative efficiency** occurs when production is in accordance with consumer preferences. Markets tend to be efficient because they promote competition and facilitate voluntary exchange. With **voluntary exchange**, both the buyer and the seller of a product are made better off by the transaction. We know that they are both made better off because, otherwise, the buyer would not have agreed to buy the product or the seller would not have agreed to sell it. Productive efficiency is achieved when competition among firms forces them to produce goods and services at the lowest cost. Allocative efficiency is achieved when the combination of competition among firms and voluntary exchange between firms and consumers results in firms producing the mix of goods and services that consumers prefer the most. Competition will result in firms continuing to produce and sell goods and services as long as the additional benefit to consumers is greater than the additional cost of production. In this way, the mix of goods and services produced will match consumer preferences.

Although markets promote efficiency, they don't guarantee it. Inefficiency can arise from various sources. For instance, it may take some time for firms to learn how to efficiently produce a good or service. When Blu-ray players were introduced, firms did not instantly achieve productive efficiency because it took several years to discover the lowest-cost method of producing this good. As we will discuss in later chapters, inefficiency can also arise if governments interfere with voluntary exchange in markets. For example, many governments limit the imports of some goods from foreign countries. This limitation reduces efficiency by keeping goods from being produced at the lowest cost. The production of some goods damages the environment. In this case, government intervention can increase efficiency because without such intervention, firms may ignore the costs of environmental damage and thereby fail to produce the goods at the lowest possible cost.

An economically efficient outcome is not necessarily desirable. Many people prefer economic outcomes that they consider fair or equitable, even if those outcomes are less efficient. **Equity** is harder to define than efficiency because there isn't an agreed-upon definition of fairness. For some people, equity means a more equal distribution of economic benefits than would result from an emphasis on efficiency alone. For example, some people support raising taxes on people with higher incomes to provide the funds for programs that aid the poor. Although governments may increase equity by reducing the incomes of high-income people and increasing the incomes of the poor, efficiency may be reduced. People have less incentive to open new businesses, work hard, and save if the government takes a significant amount of the income they earn from working or saving. The result is that fewer goods and services are produced, and less saving takes place. As this example illustrates, *there is often a trade-off between efficiency and equity*. Government policymakers frequently confront this trade-off.

1.3 Economic Models

LEARNING OBJECTIVE: Describe the role of models in economic analysis.

As mentioned at the start of the chapter, economic models are simplified versions of reality. Many professions rely on models: An engineer may use a computer model of a bridge to help test whether it will withstand high winds, or a biologist may make a

physical model of a nucleic acid to better understand its properties. Economists rely on economic models, or theories, to analyze real-world issues ranging from the role of government in monitoring smart devices to whether a society should redistribute income. (This book uses the words *model* and *theory* interchangeably.) One purpose of economic models is to make economic ideas sufficiently explicit and concrete so that individuals, firms, or the government can use them to make decisions. For example, we will see in Chapter 3 that the model of demand and supply is a simplified version of how the prices of products are determined by the interactions among buyers and sellers in markets.

Economists use economic models to answer questions such as, “Will the European Union (EU) have a sufficient number of doctors in 2020?” Economists at the European Commission (EC) build models that allow them to forecast future employment in different occupations. These models enable the EC to forecast how many doctors there are likely to be at a future date. Economists also use models to forecast the demand for medical services. By separately forecasting the number of doctors and the demand for medical services, these models provide a forecast of whether there will be a sufficient number of doctors in 2020. As mentioned at the beginning of the chapter, economists at the EC have used models to forecast that there will be a shortage of 230,000 physicians in the 28 European Union (EU) nations by 2020.

Sometimes economists use an existing model to analyze a real-world problem or issue, but in other cases, they have to develop a new model. To develop a model, economists generally follow these steps:

1. Decide on the assumptions to use in developing the model.
2. Formulate a testable hypothesis.
3. Use economic data to test the hypothesis.
4. Revise the model if it fails to explain the economic data well.
5. Retain the revised model to help answer similar economic questions in the future.

The Role of Assumptions in Economic Models

Any model is based on making assumptions because models have to be simplified to be useful. For example, economic models make *behavioral assumptions* about the motives of consumers and firms. Economists assume that consumers will buy the goods and services that will maximize their well-being or their satisfaction. Similarly, economists assume that firms act to maximize their profits. These assumptions are simplifications because they do not describe the motives of every consumer and every firm. How can we know whether the assumptions in a model are too simplified or too limiting? We can determine the usefulness of assumptions by forming hypotheses based on the assumptions and then testing the hypotheses using real-world information.

MyEconLab Concept Check

Forming and Testing Hypotheses in Economic Models

An **economic variable** is something measurable that can have different values, such as the incomes of doctors. An economic hypothesis in an economic model usually upholds a causal relationship. An example of a hypothesis is the supposition that the demanding working conditions and the relatively low-paying jobs in the health care industry will result in a decline in the number of new entrants into the industry across the European Union (EU) till 2020. In this case, the hypothesis states that the main causes or reasons behind fewer doctors entering health care are lower incomes and demanding work conditions.

A hypothesis is a proposed explanation or an anticipated supposition that requires further investigation. To test the validity of a hypothesis, statistics on the relevant economic variables must be analyzed. In our example, on the one hand we need to test the possible causality between the phenomenon of shortages of physicians, and on the other hand we need to test the lower income and poor working conditions. The testing

Economic variable Something measurable that can have different values, such as the incomes of doctors.

of hypotheses is quite a complex task due to various reasons. First, it may be true that two phenomena are correlated; that is, they happen at the same time, but we need to further investigate whether a relation actually does exist or whether this correlation is due to either pure chance or other underlying factors. For example, it is vital to test if the shortage of physicians in the EU was caused by other variables, like the rise in new technologies that require new skills or the chronic conditions of the aging population that oblige further competences. Second, many economic variables change over time. Going back to our example, it may be that the lower pay is not unique to the health sector since all occupations have suffered a decline in financial compensations in the aftermath of the Global Financial Crisis of 2008 and the European debt crisis of 2012. Third, it is quite common that economists either use different economic models to test hypotheses or even disagree over how they interpret the statistical methodologies used to test the hypothesis.

At this stage we must emphasize that the most important distinguishing feature of a hypothesis is its testability and the measurability of all underlying variables. If these preconditions are absent, postulations are considered as mere value judgments that can neither be confidently proved nor disproved.

We also need to underscore that when economists build a hypothesis, they expect that the economic models used will help them to either accept or reject the hypothesis. In many instances, when statistical analysis is inadequate, economists cannot readily accept a hypothesis, but require further statistical analysis to be undertaken before fully accepting the hypothesis. Conversely, if only few sets of data show low levels of correlation, economists require further investigations rather than rejection of the hypothesis. In such cases, economists require more data sets and further statistical analysis to readily accept or reject a hypothesis. However, if the data still rejects the hypothesis, then economists can either refine some of the assumptions of their economic model or totally replace the original hypothesis with an alternate one. For example, if the data rejects the hypothesis that lower pay reduces the number of new entrants into medical school, then the economic model may be refined to include other assumptions, such as shorter training periods and higher pay received by practicing nurses that tempts students to join nursing rather than medical schools.

The EC has assigned the Directorate General of Health and Food Safety to the task of building economic models for the health sector and constantly analyzing the accuracy of its past forecasts. Among the assumptions that it refined in its forecasting models is that in addition to clinical knowledge, physicians need to acquire new skills that enable distant or e-diagnostic services and technical know-how to work with new technologies and medical appliances. Another assumption that was previously overlooked is the close attention that is now needed by the increasing aging population suffering from multiple chronic conditions. Refining the assumptions helps the EC make better projections of occupational training, education, and employment in the health care sector.

The process of developing models, testing hypotheses, and revising models occurs not just in economics but also in disciplines such as physics, chemistry, and biology. This process is often referred to as the *scientific method*. Economics is a *social science* because it applies the scientific method to the study of the interactions among individuals.

Positive and Normative Analysis

Throughout this book, as we build economic models and use them to answer questions, bear in mind the following important distinction: **Positive analysis** is concerned with *what is*, and **normative analysis** is concerned with *what ought to be*. Economics is about positive analysis, which measures the costs and benefits of different courses of action.

We can use the federal government's minimum wage law to compare positive and normative analysis. In 2015, under this law, it was illegal for an employer to hire

Normative analysis Analysis concerned with what ought to be.

a worker at a wage less than \$7.25 per hour. Without the minimum wage law, some firms and workers would voluntarily agree to a lower wage. Because of the minimum wage law, some workers have difficulty finding jobs, and some firms end up paying more for labor than they otherwise would have. A positive analysis of the federal minimum wage law uses an economic model to estimate how many workers have lost their jobs because of the law, its effect on the costs and profits of businesses, and the gains to workers receiving the minimum wage. After economists complete this positive analysis, the decision as to whether the minimum wage law is a good or a bad idea is a normative one and depends on how people evaluate the trade-off involved. Supporters of the law believe that the losses to employers and workers who are unemployed as a result of the law are more than offset by the gains to workers who receive higher wages than they would without the law. Opponents of the law believe the losses are greater than the gains. The assessment by any individual depends, in part, on that person's values and political views. The positive analysis an economist provides would play a role in the decision but can't by itself decide the issue one way or the other.

In each chapter, you will see a *Don't Let This Happen to You* box like the one below. These boxes alert you to common pitfalls in thinking about economic ideas. After reading this box, test your understanding by working the related problem that appears at the end of the chapter.

Don't Let This Happen to You

Don't Confuse Positive Analysis with Normative Analysis

"Economic analysis has shown that the minimum wage law is a bad idea because it causes unemployment." Is this statement accurate? As of 2015, the federal minimum wage law prevents employers from hiring workers at a wage of less than \$7.25 per hour. This wage is higher than some employers are willing to pay some workers. If there were no minimum wage law, some workers who currently cannot find any firm willing to hire them at \$7.25 per hour would be able to find employment at a lower wage. Therefore, positive economic analysis indicates that the minimum wage law causes unemployment. (In Chapter 4, we'll explore why economists disagree about *how much* unemployment the minimum wage law causes.) But, some workers who have

jobs benefit from the minimum wage law because they are paid a higher wage than they otherwise would be. In other words, the minimum wage law creates both losers—the workers who become unemployed and the firms that have to pay higher wages—and winners—the workers who receive higher wages.

Should we value the gains to the winners more than we value the losses to the losers? The answer involves normative analysis. Positive economic analysis can show the consequences of a particular policy, but it cannot tell us whether the policy is "good" or "bad." So, the statement at the beginning of this box is inaccurate.

Economics as a Social Science

Because economics studies the actions of individuals, it is a social science. Economics is therefore similar to other social science disciplines, such as psychology, political science, and sociology. As a social science, economics considers human behavior—particularly decision-making behavior—in every context, not just in the context of business. Economists have studied issues such as how families decide on the number of children to have, why people have difficulty losing weight or attaining other goals, and why people often ignore relevant information when making decisions. Economics also has much to contribute to questions of government policy. As we will see throughout this book, economists have played an important role in formulating government policies in areas such as the environment, health care, and poverty.

Should Medical School Be Free?

The U.S. population continues to increase, which by itself would increase the demand for medical services. In addition, the average age of the population is rising, and older people need more medical care than do younger people. So, over time, the number of doctors needs to increase. As mentioned at the beginning of this chapter, the U.S. Health Resources and Services Administration (HRSA) estimates that the number of doctors needed to provide patient care will rise to 922,000 in 2020.

Can we be sure that these additional doctors will be available in 2020? The HRSA forecasts that, in fact, there will be a shortage of 55,600 doctors in 2020. The bulk of that shortage is likely to be in primary care physicians, or family doctors. As we will discuss in later chapters, ordinarily we expect that when consumers want more of a product, higher wages and salaries and more job openings will attract workers to that industry. For example, during the U.S. housing boom of the mid-2000s, the number of workers in the building trades—carpenters, plumbers, roofers, and others—increased rapidly. But producing more doctors is a long process. After completing an undergraduate education, a doctor spends four years in medical school and

Should these medical students have to pay tuition?

then three to five years at a teaching hospital, pursuing a residency in a particular field of medicine. Apparently convinced that hospitals will not train enough doctors unless they get help, Congress contributes \$10 billion per year to teaching hospitals, based on the number of residents they train.

Peter Bach of the Sloan-Kettering Cancer Center and Robert Kocher of the Brookings Institution have proposed that medical schools should charge no tuition. They argue that nearly all students graduate from medical school owing money on student loans, with the average student owing more than \$160,000. We might expect that these debts, although large, would *not* deter students from applying to medical school, because in 2015, the average income of physicians was more than \$250,000 per year. Bach and Kocher argue, however, that the high cost of medical school has two bad outcomes: (1) Some good students do not apply because they either do not want to be saddled with such large debts or are unable to borrow sufficient money, and (2) many students avoid going into primary care—where average incomes are \$190,000—in favor of specialties such as plastic surgery or anesthesiology—where average incomes are \$325,000. Teaching hospitals pay doctors a salary of about \$50,000 per year during their residencies. Bach and Kocher propose that hospitals continue to pay residents who pursue primary care but not pay residents who specialize. The money that hospitals would otherwise pay to these residents would be paid to medical schools instead to finance the free tuition. The plan would give residents an incentive to pursue primary care rather than to specialize. Critics of the Bach and Kocher proposal have questioned whether many students capable of being admitted to medical school actually are deterred by medical school tuition. They also question whether many residents who intend to specialize would choose primary care instead, even if specializing means they have to borrow to meet living expenses rather than pay for them with a hospital salary.

Like many other policy debates, the debate over whether changes should be made in how medical school is paid for has positive and normative elements. By gathering data and using economic models, we can assess some of the quantitative claims made by each side in the debate: What role does tuition play in a student's decision about whether to attend medical school? Have tuition increases had a large effect or a small effect on the number of applications to medical school? How do changes in expected future incomes affect the decisions of medical students about which specialty to choose? These are all positive questions, so it is possible to formulate quantitative answers. Ultimately, though, this debate also has a normative element. For instance, some doctors, economists, and policymakers argue that it is important that people living in low-income or rural areas have improved access to health care, so they are willing to support policies that would

redirect medical students away from specialized fields and toward primary care. Other doctors, economists, and policymakers believe that medical students who enter specialized fields make a larger contribution to society than do students who enter primary care. A disagreement of this type is unlikely to be resolved by building models and analyzing data because the issue involved is essentially normative.

In 2010, President Obama and Congress enacted the Patient Protection and Affordable Care Act, which made major changes to the U.S. health care system. Most of the changes were in effect by 2015. Additional changes are likely as policymakers grapple with the increasing costs of health care. Whether Congress and the president will enact policies intended to increase the number of family doctors remains to be seen.

Microeconomics and Macroeconomics

LEARNING OBJECTIVE: Distinguish between microeconomics and macroeconomics.

Economic models can be used to analyze decision making in many areas. We group some of these areas together as *microeconomics* and others as *macroeconomics*. **Microeconomics** is the study of how households and firms make choices, how they interact in markets, and how the government attempts to influence their choices. **Macroeconomics** is the study of the economy as a whole, including topics such as inflation, unemployment, and economic growth. Table 1.1 gives examples of microeconomic and macroeconomic issues.

The division between microeconomics and macroeconomics is not a bright line. Many economic situations have *both* a microeconomic aspect and a macroeconomic aspect. For example, the level of total investment by firms in new machinery and equipment helps to determine how rapidly the economy grows—which is a macroeconomic issue. But to understand how much new machinery and equipment firms decide to purchase, we have to analyze the incentives individual firms face—which is a microeconomic issue.

[MyEconLab Concept Check](#)

Microeconomics The study of how households and firms make choices, how they interact in markets, and how the government attempts to influence their choices.

Macroeconomics The study of the economy as a whole, including topics such as inflation, unemployment, and economic growth.

Examples of microeconomic issues

- How consumers react to changes in product prices
- How firms decide what prices to charge for the products they sell
- Which government policy would most efficiently reduce teenage smoking
- What are the costs and benefits of approving the sale of a new prescription drug
- What is the most efficient way to reduce air pollution

Examples of macroeconomic issues

- Why economies experience periods of recession and increasing unemployment
- Why, over the long run, some economies have grown much faster than others
- What determines the inflation rate
- What determines the value of the U.S. dollar
- Whether government intervention can reduce the severity of recessions

A Preview of Important Economic Terms

LEARNING OBJECTIVE: Define important economic terms.

In the following chapters, you will encounter certain important terms again and again. Becoming familiar with these terms is a necessary step in learning economics. Here we provide only a brief introduction to some of these terms. We will discuss them all in greater depth in later chapters:

- *Firm, company, or business.* A *firm* is an organization that produces a good or service. Most firms produce goods or services to earn profits, but there are also nonprofit

firms, such as universities and some hospitals. Economists use the terms *firm*, *company*, and *business* interchangeably.

- *Entrepreneur.* An *entrepreneur* is someone who operates a business. In a market system, entrepreneurs decide what goods and services to produce and how to produce them. An entrepreneur starting a new business puts his or her own funds at risk. If an entrepreneur is wrong about what consumers want or about the best way to produce goods and services, his or her funds can be lost. Losing money in a failed business is not unusual: In the United States, about half of new businesses close within four years. Without entrepreneurs willing to assume the risk of starting and operating businesses, economic progress would be impossible in a market system.
- *Innovation.* There is a distinction between an *invention* and an *innovation*. An *invention* is a new good or a new process for making a good. An *innovation* is the practical application of an invention. (*Innovation* may also be used more broadly to refer to any significant improvement in a good or in the means of producing a good.) Much time often passes between the appearance of a new idea and its development for widespread use. For example, the Wright brothers first achieved self-propelled flight at Kitty Hawk, North Carolina, in 1903, but the Wright brothers' plane was very crude, and it wasn't until the introduction of the DC-3 by Douglas Aircraft in 1936 that regularly scheduled intercity airline flights became common in the United States. Similarly, the first digital electronic computer—the ENIAC—was developed in 1945, but the first IBM personal computer was not introduced until 1981, and widespread use of computers did not have a significant effect on the productivity of U.S. business until the 1990s.
- *Technology.* A firm's *technology* is the processes it uses to produce goods and services. In the economic sense, a firm's technology depends on many factors, such as the skill of its managers, the training of its workers, and the speed and efficiency of its machinery and equipment.
- *Goods.* *Goods* are tangible merchandise, such as books, computers, or Blu-ray players.
- *Services.* *Services* are activities done for others, such as providing haircuts or investment advice.
- *Revenue.* A firm's *revenue* is the total amount received for selling a good or service. We calculate it by multiplying the price per unit by the number of units sold.
- *Profit.* A firm's *profit* is the difference between its revenue and its costs. Economists distinguish between *accounting profit* and *economic profit*. In calculating accounting profit, we exclude the costs of some economic resources that the firm does not pay for explicitly. In calculating economic profit, we include the opportunity costs of all resources used by the firm. When we refer to *profit* in this book, we mean economic profit. It is important not to confuse *profit* with *revenue*.
- *Household.* A *household* consists of all persons occupying a home. Households are suppliers of factors of production—particularly labor—used by firms to make goods and services. Households also demand goods and services produced by firms and governments.
- *Factors of production, economic resources, or inputs.* Firms use *factors of production* to produce goods and services. The main factors of production are labor, capital, natural resources—including land—and entrepreneurial ability. Households earn income by supplying the factors of production to firms. Economists use the terms *factors of production*, *economic resources*, and *inputs* interchangeably.
- *Capital.* In everyday speech, the word *capital* can refer to *financial capital* or to *physical capital*. Financial capital includes stocks and bonds issued by firms, bank accounts, and holdings of money. In economics, though, *capital* refers to physical capital, which includes manufactured goods that are used to produce other goods and

services. Examples of physical capital are computers, factory buildings, machine tools, warehouses, and trucks. The total amount of physical capital available in a country is referred to as the country's *capital stock*.

- *Human capital*. *Human capital* refers to the accumulated training and skills that workers possess. For example, college-educated workers generally have more skills and are more productive than workers who have only high school degrees; therefore, college-educated workers have more human capital.

Economics in Your Life

Will There Be Plenty of Jobs Available in the Health Care Industry?

At the beginning of this chapter, we posed the question: “On what factors does the European Commission (EC) base forecasts on health care job availability, and how reliable are these forecasts?” To help design future action plans, forecasts are based on economic models. However, it would be incorrect to consider forecasts as given truths. Not only may unpredictable circumstances occur, but the results may also be diverse when economists use different models. For example, in 2008 the World Health Organization (WHO) used two models to forecast the demand for physicians. In the first model, 10 European nations were projected to suffer from shortages of physicians, while in the second model there was no forecasted shortage in any European nation. To increase the reliability of forecasts, EC economists include many variables in their economic models, such as potential birth and death rates; general health indicators including obesity, alcohol consumption, and smoking; the aging population; retiring medical workers; and new entrants into medical schools.

Conclusion

Economics is a group of useful ideas about how individuals make choices. Economists have put these ideas into practice by developing economic models. Consumers, business managers, and government policymakers use these models every day to help make choices. In this book, we explore many key economic models and give examples of how to apply them in the real world.

Reading the news is an important part of understanding the current business climate and learning how to apply economic concepts to a variety of real-world events. At the end of each of the first four chapters, you will see a two-page feature titled *An Inside Look*. This feature consists of an excerpt from an article that relates to the company or economic issue introduced at the start of the chapter and also to the concepts discussed in the chapter. A summary and an analysis with a supporting table or graph highlight the key economic points of the article. Read *An Inside Look* for a discussion of how technological change, such as the development of smart medical devices, affects the way doctors provide health care. Test your understanding by answering the *Thinking Critically* questions.

Google Smart Contact Lens Focuses On Healthcare Billions

a Google is developing a smart contact lens, with pharmaceutical giant Novartis, to help patients manage diabetes—in one of a number of moves focused squarely on billions of dollars of potential revenue available across the total digital healthcare market.

As technology moves further into treatment with remote consultations, monitoring and operations, robotic treatments, and advanced digital diagnosis, Google has seen the opportunity to apply its own eyewear technology (up until now limited as glasses called Google Glass) to the healthcare field.

Google's 3D mobile technology and its offering around health record digitization form potential other strands of its expansion in the health market. Last month, it released the Google Fit platform to track exercise and sleep, among other health factors—but it is far from alone, as Apple and Samsung offer similar systems in that area.

b Today, under a new development and licensing deal between Google and the Alcon eyewear division at

Novartis, the two companies said they will create a smart contact lens that contains a low power microchip and an almost invisible, hair-thin electronic circuit. The lens can measure diabetics' blood sugar levels directly from tear fluid on the surface of the eyeball. The system sends data to a mobile device to keep the individual informed.

Google co-founder Sergey Brin said the company wanted to use “the latest technology in ‘minituarisation’ of electronics” in order to improve people’s “quality of life”.

Novartis chief executive Joe Jimenez added that technology as a whole, starting with smart eyewear, could be used to “manage human diseases,” and indicated that diseases will be mapped in the body using a range of other devices in the future—many of which are in development across universities and research laboratories.

An official timescale for the product’s development and commercialization has not been made public, though Jimenez said in *Reuters* and *WSJ* interviews respectively that the company “would hope to be able to commercialize it within about five years”, adding that it was expected to create a “large revenue stream”.

c The combination of Google’s technology background and Novartis’

pharmaceutical knowledge would help meet “unmet medical needs,” Jimenez claimed.

The pharmaceutical firm is also looking into how to enable the contact lens technology to assess long sighted people’s vision and autofocus it on what they are looking at, working rather like an automatic camera lens when taking a picture. Such technology would help them avoid the need for glasses when reading or looking at other nearby objects.

The Google team involved in the contact lens development is called Google[x], and it focuses on “finding new solutions to big global problems” in healthcare and beyond, according to the companies.

The secretive Google[x] facility operates in Mountain View, California, and one of its most high profile projects has been a self driving car. It is also working closely on speech recognition, balloon powered internet access for rural areas, wind power, and technology for the Internet of Things—in which internet connected home, personal and city objects communicate with each other and take automatic action when different events take place.

Key Points in the Article

Google is adding to its growing list of technological innovations by partnering with Swiss pharmaceutical company Novartis to develop smart contact lenses to help patients manage diabetes. A microchip and electronic circuit in the contact lenses will measure blood sugar levels from tear fluids on the surface of the eye and transmit the data to a mobile device. Novartis is also exploring ways to incorporate autofocus technology in the contact lens, which could eliminate the need for reading glasses. The smart contact lens is just one of a growing number of products being developed in the multibillion-dollar, rapidly expanding digital health care market. Novartis chief executive Joe Jimenez hopes to see the smart contact lens available in the market within five years.

Analyzing the News

a Advances in technology are having a profound effect on many sectors of the economy, and one of the fastest-growing sectors is the digital health care market. Rapid improvements in smartphone technology have played a large role in expanding the use of smart medical devices. The future of health care may be greatly affected by partnerships between high-tech firms like Google and health industry firms like Novartis. These partnerships can lead to the development of smart devices

designed to facilitate and improve medical diagnoses and conditions.

b According to the Centers for Disease Control and Prevention (CDC), diabetes ranks seventh among the leading causes of death in the United States, with more than 75,000 deaths in 2012 attributed to the disease. The total estimated cost of diabetes that year was \$245 billion, which included the costs of direct medical care as well as the costs associated with disability, work loss, and premature death. In 2012, the CDC estimated that 28.9 million people in the United States age 20 or older had diabetes, and almost 28 percent of those cases were undiagnosed. The table below shows these data as well as data on the number of new, diagnosed cases of diabetes. Given the number of people suffering from diabetes, the development of the smart contact lens has the potential to help patients manage their disease. For example, being able to monitor blood sugar levels via the contact lens and a smartphone could be more convenient and less painful than the common finger-prick testing method and might therefore encourage more people to regularly monitor their diabetes. An effective and relatively inexpensive smart contact lens could end up saving not only time and money but also lives.

c The health care industry is growing as well as changing, and technology is fueling a large part of the change. Smart

medical devices are still in their infancy, but rapid technological advancement has led many new firms to enter this industry, introducing innovative new products. As the average age of the U.S. population continues to increase, and as people spend more time and resources on maintaining good health, smart medical devices may revolutionize the way health care is administered. This revolution will benefit not only those companies involved with the development of new products but also health care professionals and their patients.

Thinking Critically

1. One key economic idea is that people respond to economic incentives. What economic incentives are Google and Novartis responding to?
2. Some diabetic patients need to monitor their condition by pricking their finger for blood to check blood sugar levels. If these patients could instead use the smart contact lens, it could improve the effectiveness of monitoring and, therefore, treatment. Develop an economic model to analyze the relationship between using the smart contact lens or the finger-prick method of monitoring blood sugar levels and the number of diabetes-related deaths in the United States. Use information from the article to explain the steps you would take to develop this model.

Three Key Economic Ideas, pages 62–66

LEARNING OBJECTIVE: Explain these three key economic ideas: People are rational; people respond to economic incentives; and optimal decisions are made at the margin.

Summary

Economics is the study of the choices consumers, business managers, and government officials make to attain their goals, given their scarce resources. We must make choices because of **scarcity**, which means that although our wants are unlimited, the resources available to fulfill those wants are limited. Economists assume that people are rational in the sense that consumers and firms use all available information as they take actions intended to achieve their goals. Rational individuals weigh the benefits and costs of each action and choose an action only if the benefits outweigh the costs. Although people act from a variety of motives, ample evidence indicates that they respond to economic incentives. Economists use the word **marginal** to mean extra or additional. The optimal decision is to continue any activity up to the point where the marginal benefit equals the marginal cost.

- 1.2 What is scarcity? Why is scarcity central to the study of economics?

Problems and Applications

- 1.3 Comment on the assumption common to most economic models that all individuals are rational and make optimal decisions in response to economic incentives.
- 1.4 According to the FBI Bank Crime Statistics, there were nearly 4,000 bank robberies in the United States in 2014. The FBI claims that banks have made themselves easy targets by refusing to install clear acrylic partitions, called *bandit barriers*, that separate bank tellers from the public. According to a special agent with the FBI, “Bandit barriers are a great deterrent. We’ve talked to guys who rob banks, and as soon as they see a bandit barrier, they go find another bank.” Despite this finding, many banks have been reluctant to install these barriers. Wouldn’t banks have a strong incentive to install bandit barriers to deter robberies? Why, then, do so many banks not do so?

- 1.5 The grading system plays an important role in student learning. In their book *Effective Grading: A Tool for Learning and Assessment in College*, Barbara Walvoord and Virginia Anderson state that “grading infuses everything that happens in the classroom.” They also argue that grading “needs to be acknowledged and managed from the first moment that an instructor begins planning a class.”
 - a. How could the grading system a teacher uses affect the incentives of students to learn the course material?
 - b. If teachers put too little weight in the grading scale on a certain part of the course, such as readings outside the textbook, how might students respond?
 - c. Teachers often wish that students came to class prepared, having read the upcoming material. How could a teacher design the grading system to motivate students to come to class prepared?

- 1.6 In the United Kingdom patients can access non-emergency hospital treatment for free if referred by a family doctor, also known as a general practitioner (GP). A patient gets in contact with the National Health Service (NHS) via a GP almost nine times out of ten. GPs often work in practices with two to five doctors. Practices are open during weekdays from 8 A.M. to 5 P.M. and are closed during weekends. Patients need to book an appointment to see their GP. In 2013, the Prime Minister of England introduced a Challenge Fund initiative, investing £50 million to pilot the new scheme, under which a limited number of practices have been asked to stay open during weekends.
 - a. As a result of weekend access to primary care, do you think that the costs incurred by the NHS to treat patients in the accident and emergency (A&E) departments has increased or decreased? Briefly explain.
 - b. A newly elected government has recently expressed the intention to implement important changes to the way patients access GP services. Given your answer to part (a), do you think that the new government is likely

to recommend universal GP access seven days a week by 2020? Briefly explain.

- c. How might the government have failed to correctly forecast the costs of weekend opening hours? Briefly explain.

- 1.7 (Related to the Making the Connection on page 63)** Many universities and corporations offer a health and wellness program that helps their employees improve or maintain their health and get paid (a relatively small amount) for doing so. The programs vary but typically consist of employees completing a health assessment, receiving a program for healthy living, and monitoring their monthly health activities.

- Why would universities and corporations pay employees to improve or maintain their health?
- How does health insurance affect the incentive of employees to improve or maintain their health?
- Would a wellness program increase or decrease the health insurance premiums that an insurance company would charge the university or corporation to provide insurance coverage? Briefly explain.

- 1.8 (Related to the Making the Connection on page 63)** Jay Bhattacharya and Kate Bundorf of Stanford University have found evidence that people who are obese and who work for firms that provide health insurance receive lower wages than workers at those firms who are not obese. At firms that do not provide health insurance, obese workers do not receive lower wages than workers who are not obese.

- Why might firms that provide workers with health insurance pay a lower wage to obese workers than to workers who are not obese?
- Is Bhattacharya and Bundorf’s finding relevant to the question of whether health insurance provides people with an incentive to become obese? Briefly explain.

- 1.9 (Related to Solved Problem 1.1 on page 65)** The United Kingdom’s big four retailers—Tesco, Asda, Sainsbury’s, and Morrisons—have been facing fierce competition from German competitors Aldi and Lidl. The big four still occupy significant portions of the U.K. grocery market; Tesco occupies 28.2 percent, Asda 16.7 percent, Sainsbury’s 16.2 percent, and Morrisons 10.7 percent, while Aldi has

5.6 percent, and Lidl occupies 4.2 percent. Nonetheless, sales growth rates are clearly in favor of the two German discount retailers. Sainsbury’s grew 0.9 percent, Tesco and Morrisons both dropped 1.4 percent, while Asda lost 2.9 percent. Aldi and Lidl have grown 17.3 percent and 16 percent respectively. After reporting record annual sales in 2014, Aldi said that it will be selling goods online in the United Kingdom. However, Matthew Barnes, Aldi’s CEO, said that the retailer will not necessarily start selling food online. It will start with wine by the case, and then add non-food items in the spring. If you were Aldi’s CEO, discuss how you would go about analyzing whether to launch online sales or not. Would your decision be all or nothing—either provide online access to Aldi’s full range of products or only sell within the store without an online option?

The Economic Problem That Every Society Must Solve, pages 66–70

LEARNING OBJECTIVE: Discuss how an economy answers these questions: What goods and services will be produced? How will the goods and services be produced? Who will receive the goods and services produced?

Summary

Society faces **trade-offs**: Producing more of one good or service means producing less of another good or service. The **opportunity cost** of any activity—such as producing a good or service—is the highest-valued alternative that must be given up to engage in that activity. The choices of consumers, firms, and governments

determine what goods and services will be produced. Firms choose how to produce the goods and services they sell. In the United States, who receives the goods and services produced depends largely on how income is distributed in the marketplace. In a **centrally planned economy**, most economic decisions are made by the government. In a **market economy**, most economic decisions are made by consumers and firms. Most economies, including that

of the United States, are **mixed economies** in which most economic decisions are made by consumers and firms but in which the government also plays a significant role. There are two types of efficiency: productive efficiency and allocative efficiency. **Productive efficiency** occurs when a good or service is produced at the lowest possible cost. **Allocative efficiency** occurs when production corresponds with consumer preferences. **Voluntary exchange** is a situation that occurs in markets when both the buyer and the seller of a product are made better off by the transaction. **Equity** is more difficult to define than efficiency, but it usually involves a fair distribution of economic benefits. Government policymakers often face a trade-off between equity and efficiency.

Economic Models, pages 70–75

LEARNING OBJECTIVE: Describe the role of models in economic analysis.

Summary

An **economic variable** is something measurable that can have different values, such as the wages of software programmers. Economists rely on economic models when they apply economic ideas to real-world problems. **Economic models** are simplified versions of reality used to analyze real-world economic situations. Economists accept and use an economic model if it leads to hypotheses that are confirmed by statistical analysis. In many cases, the acceptance is tentative, however, pending the gathering of new data or further statistical analysis. Economics is a *social science* because it applies the scientific method to the study of the interactions among individuals. Economics is concerned with positive analysis rather than normative analysis. **Positive analysis** is concerned with what is. **Normative analysis** is concerned with what ought to be. As a social science, economics considers human behavior in every context of decision making, not just in business.

Using Graphs and Formulas

LEARNING OBJECTIVE: Use graphs and formulas to analyze economic situations.

Graphs are used to illustrate key economic ideas. Graphs appear not just in economics textbooks but also on Web sites and in newspaper and magazine articles that discuss events in business and economics. Graphs serve two useful purposes: (1) They simplify economic ideas, and (2) they make the ideas more concrete so they can be applied to real-world problems. Economic and business issues can be complicated, but a graph can help cut through complications and highlight the key relationships needed to understand the issue. In that sense, a graph can be like a street map.

Suppose you take a bus to New York City to see the Empire State Building. After arriving at the Port Authority Bus Terminal, you will probably use a map similar to this one to find your way to the Empire State Building.

Maps are simplified versions of reality. This map shows the streets in this part of New York City and some of the most important buildings. The map does not show stores, most buildings, or the names, addresses, and telephone numbers of the people who live and work in the area. In fact, the map shows almost nothing about the messy reality of life in this section of New York City, except how the streets are laid out, which is the essential information you need to get from the Port Authority Bus Terminal to the Empire State Building.

Street map of New York City. Copyright © 2011 City Maps Inc. Reprinted by permission.

Think about someone who says, “I know how to get around in the city, but I just can’t figure out how to read a map.” It certainly is possible to find your destination in a city without a map, but it’s a lot easier with one. The same is true of using graphs in economics. It is possible to arrive at a solution to a real-world problem in economics and business without using graphs, but it is usually a lot easier if you use them.

With practice, you will become familiar with the graphs and formulas in this text, and you will know how to use them to analyze problems that would otherwise seem very difficult. What follows is a brief review of how graphs and formulas are used.

Graphs of One Variable

Figure 1A.1 displays values for *market shares* in the U.S. automobile market, using two common types of graphs. Market shares show the percentage of industry sales accounted for by different firms. In this case, the information is for groups of firms: the “Big Three”—Ford, General Motors, and Chrysler—as well as Japanese, European, and Korean firms. Panel (a) displays the information about market shares as a *bar graph*, where the market share of each group of firms is represented by the height of its bar. Panel (b) displays the same information as a *pie chart*, where the market share of each group of firms is represented by the size of its slice of the pie.

Information about an economic variable is also often displayed in a *time-series graph*, which shows on a coordinate grid how the values of a variable change over time. In a coordinate grid, we can measure the value of one variable along the vertical axis (or *y-axis*) and the value of another variable along the horizontal axis (or *x-axis*). The point where the vertical axis intersects the horizontal axis is called the *origin*. At the origin, the value of both variables is zero. The points on a coordinate grid represent values of the two variables.

In Figure 1A.2, we measure the number of automobiles and trucks sold worldwide by Ford Motor Company on the vertical axis, and we measure time on the horizontal axis. In time-series graphs, the height of the line at each date shows the value of the

variable measured on the vertical axis. Both panels of Figure 1A.2 show Ford's worldwide sales during each year from 2003 to 2014. The difference between panel (a) and panel (b) illustrates the importance of the scale used in a time-series graph. In panel (a), the vertical axis starts at 0, and the distance between each pair of values shown is the same. In this panel, the decline in Ford's sales during 2008 and 2009 appears relatively small. In panel (b), the scale on the vertical axis is truncated, which means that although it starts at zero, it jumps to 4.5 million. As a result, the distance on the vertical axis from 0 to 4.5 million is much smaller than the distance from 4.5 million to 5.0 million. The slashes (//) near the bottom of the axis indicate that the scale is truncated. In panel (b), the decline in Ford's sales during 2008 and 2009 appears much larger than in panel (a). (Technically, the horizontal axis in both panels is also truncated because we start with 2003, not 0.)

MyEconLab Concept Check

Graphs of Two Variables

We often use graphs to show the relationship between two variables. Suppose you are interested in the relationship between the price of a cheese pizza and the quantity of pizzas sold per week in the town of Statesboro, Georgia. A graph showing the relationship between the price of a good and the quantity of the good demanded at each price is called a *demand curve*. (As we will discuss later, in drawing a demand curve for a good, we have to hold constant any variables other than price that might affect the willingness of consumers to buy the good.) Figure 1A.3 shows the data collected on price and quantity. The figure shows a two-dimensional grid on which we measure the price of pizza along the *y*-axis and the quantity of pizza sold per week along the *x*-axis. Each point on the grid represents one of the price and quantity combinations listed in the table. We can connect the points to form the demand curve for pizza in Statesboro, Georgia. Notice that the scales on both axes in the graph are truncated. In this case, truncating the axes allows the graph to illustrate more clearly the relationship between price and quantity by excluding low prices and quantities.

MyEconLab Concept Animation

Figure 1A.3

Plotting Price and Quantity Points in a Graph

The figure shows a two-dimensional grid on which we measure the price of pizza along the vertical axis (or y -axis) and the quantity of pizza sold per week along the horizontal axis (or x -axis). Each point on the grid represents one of the price and quantity combinations listed in the table. By connecting the points with a line, we can better illustrate the relationship between the two variables.

Price (dollars per pizza)	Quantity (pizzas per week)	Points
\$15	50	A
14	55	B
13	60	C
12	65	D
11	70	E

As we saw in Figure 1A.2, the slashes (//) indicate that the scales on the axes are truncated, which means that numbers are omitted: On the horizontal axis numbers jump from 0 to 50, and on the vertical axis numbers jump from 0 to 11.

Slopes of Lines

Once you have plotted the data in Figure 1A.3, you may be interested in how much the quantity of pizza sold increases as the price decreases. The *slope* of a line tells us how much the variable we are measuring on the y -axis changes as the variable we are measuring on the x -axis changes. We can use the Greek letter delta (Δ) to stand for the change in a variable. The slope is sometimes referred to as the rise over the run. So, we have several ways of expressing slope:

$$\text{Slope} = \frac{\text{Change in value on the vertical axis}}{\text{Change in value on the horizontal axis}} = \frac{\Delta y}{\Delta x} = \frac{\text{Rise}}{\text{Run}}$$

Figure 1A.4 reproduces the graph from Figure 1A.3. Because the slope of a straight line is the same at any point, we can use any two points in the figure to calculate the slope of the line. For example, when the price of pizza decreases from \$14 to \$12, the quantity of pizza sold increases from 55 per week to 65 per week. Therefore, the slope is:

$$\text{Slope} = \frac{\Delta \text{Price of pizza}}{\Delta \text{Quantity of pizza}} = \frac{(\$12 - \$14)}{(65 - 55)} = \frac{-2}{10} = -0.2.$$

The slope of this line shows us how responsive consumers in Statesboro, Georgia, are to changes in the price of pizza. The larger the value of the slope (ignoring the negative sign), the steeper the line will be, which indicates that not many additional pizzas are sold when the price falls. The smaller the value of the slope, the flatter the line will be, which indicates a greater increase in pizzas sold when the price falls. MyEconLab Concept Check

Taking into Account More Than Two Variables on a Graph

The demand curve graph in Figure 1A.4 shows the relationship between the price of pizza and the quantity of pizza demanded, but we know that the quantity of any good demanded depends on more than just the price of the good. For example, the quantity of pizza demanded in a given week in Statesboro, Georgia, can be affected by other

MyEconLab Animation

Figure 1A.4

Calculating the Slope of a Line

We can calculate the slope of a line as the change in the value of the variable on the y-axis divided by the change in the value of the variable on the x-axis. Because the slope of a straight line is constant, we can use any two points in the figure to calculate the slope of the line. For example, when the price of pizza decreases from \$14 to \$12, the quantity of pizza demanded increases from 55 per week to 65 per week. So, the slope of this line equals -2 divided by 10 , or -0.2 .

variables—the price of hamburgers, whether an advertising campaign by local pizza parlors has begun that week, and so on. Allowing the values of any other variables to change will cause the position of the demand curve in the graph to change.

Suppose that the demand curve in Figure 1A.4 were drawn holding the price of hamburgers constant, at \$1.50. If the price of hamburgers rises to \$2.00, some consumers will switch from buying hamburgers to buying pizza, and more pizzas will be demanded at every price. The result on the graph will be to shift the line representing the demand curve to the right. Similarly, if the price of hamburgers falls from \$1.50 to \$1.00, some consumers will switch from buying pizza to buying hamburgers, and fewer pizzas will be demanded at every price. The result on the graph will be to shift the line representing the demand curve to the left.

The table in Figure 1A.5 shows the effect of a change in the price of hamburgers on the quantity of pizza demanded. On the graph, suppose that at first we are on the line labeled Demand curve₁. If the price of pizza is \$14 (point A), an increase in the price of

Showing Three Variables on a Graph

The demand curve for pizza shows the relationship between the price of pizzas and the quantity of pizzas demanded, holding constant other factors that might affect the willingness of consumers to buy pizza. If the price of pizza is \$14 (point A), an increase in the price of hamburgers from \$1.50 to \$2.00 increases the quantity of pizzas demanded from 55 to 60 per week (point B) and shifts us to Demand curve₂. Or, if we start on Demand curve₁ and the price of pizza is \$12 (point C), a decrease in the price of hamburgers from \$1.50 to \$1.00 decreases the quantity of pizza demanded from 65 to 60 per week (point D) and shifts us to Demand curve₃.

Graphing the Positive Relationship between Income and Consumption

In a positive relationship between two economic variables, as one variable increases, the other variable also increases. This figure shows the positive relationship between disposable personal income and consumption spending. As disposable personal income in the United States has increased, so has consumption spending.

Source: U.S. Department of Commerce, Bureau of Economic Analysis.

Year	Disposable Personal Income (billions of dollars)	Consumption Spending (billions of dollars)
2011	\$11,801	\$10,689
2012	12,384	11,083
2013	12,505	11,484
2014	12,986	11,930

hamburgers from \$1.50 to \$2.00 increases the quantity of pizzas demanded from 55 to 60 per week (point B) and shifts us to Demand curve₂. Or, if we start on Demand curve₁ and the price of pizza is \$12 (point C), a decrease in the price of hamburgers from \$1.50 to \$1.00 decreases the quantity of pizzas demanded from 65 to 60 per week (point D) and shifts us to Demand curve₃. By shifting the demand curve, we have taken into account the effect of changes in the value of a third variable—the price of hamburgers. We will use this technique of shifting curves to allow for the effects of additional variables many times in this book.

MyEconLab Concept Check

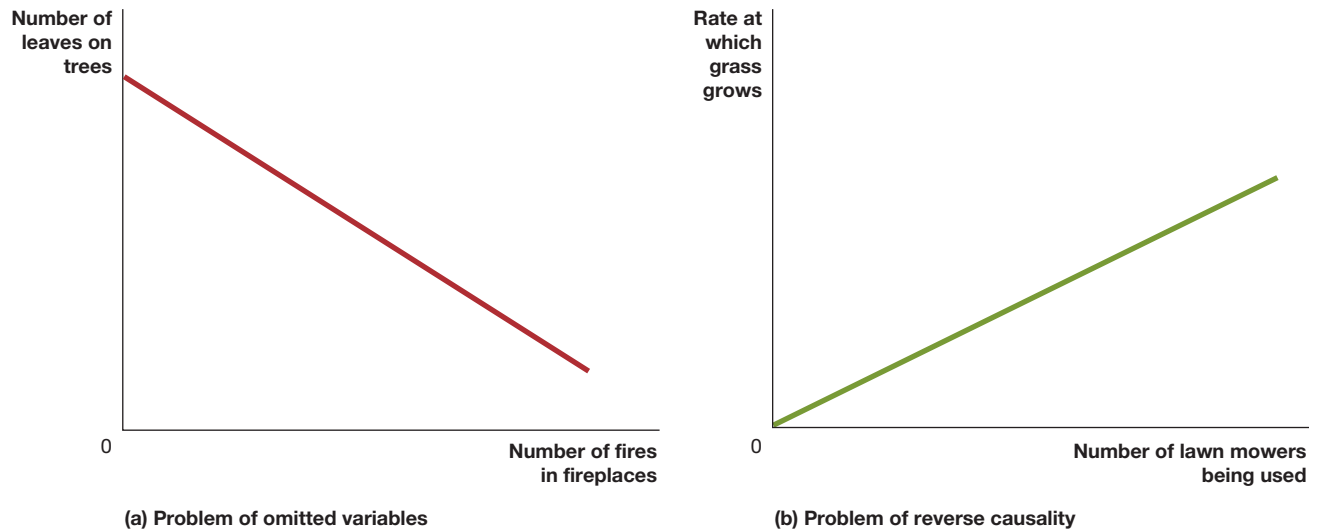

Positive and Negative Relationships

We can use graphs to show the relationships between any two variables. Sometimes the relationship between the variables is *negative*, meaning that as one variable increases in value, the other variable decreases in value. This was the case with the price of pizza and the quantity of pizzas demanded. The relationship between two variables can also be *positive*, meaning that the values of both variables increase or decrease together. For example, when the level of total income—or *disposable personal income*—received by households in the United States increases, the level of total *consumption spending*, which is spending by households on goods and services, also increases. The table in Figure 1A.6 shows the values (in billions of dollars) for income and consumption spending for 2011–2014. The graph plots the data from the table, with disposable personal income measured along the horizontal axis and consumption spending measured along the vertical axis. Notice that the points for 2012 and 2013 do not all fall exactly on the line. To examine the relationship between two variables, economists often use the straight line that best fits the data.

MyEconLab Concept Check

Determining Cause and Effect

When we graph the relationship between two variables, we usually want to draw conclusions about whether changes in one variable are causing changes in the other variable. Doing so can, however, lead to mistakes. Suppose over the course of a year you graph the number of homes in a neighborhood that have a fire burning in the fireplace and the number of leaves on trees in the neighborhood. You would get a relationship like that shown in panel (a) of Figure 1A.7: The more fireplaces in use in the neighborhood, the fewer leaves the trees have. Can we draw the conclusion from this graph that

MyEconLab Animation

Figure 1A.7 Determining Cause and Effect

Using graphs to draw conclusions about cause and effect can be hazardous. In panel (a), we see that there are fewer leaves on the trees in a neighborhood when many homes have fires burning in their fireplaces. We cannot draw the conclusion that using fireplaces causes the leaves to fall because we have an *omitted variable*—the season of the year. In panel (b), we see that

more lawn mowers are used in a neighborhood during times when the grass grows rapidly and fewer lawn mowers are used when the grass grows slowly. Concluding that using lawn mowers *causes* the grass to grow faster would be making the error of *reverse causality*.

using a fireplace causes trees to lose their leaves? We know, of course, that such a conclusion is incorrect. In spring and summer, there are relatively few fireplaces being used, and the trees are full of leaves. In the fall, as trees begin to lose their leaves, fireplaces are used more frequently. And in winter, many fireplaces are being used and many trees have lost all their leaves. The reason that the graph in Figure 1A.7 is misleading about cause and effect is that there is obviously an *omitted variable* in the analysis—the season of the year. An omitted variable is one that affects other variables, and its omission can lead to false conclusions about cause and effect.

Although in our example the omitted variable is obvious, there are many debates about cause and effect where the existence of an omitted variable has not been clear. For instance, it has been known for many years that people who smoke cigarettes suffer from higher rates of lung cancer than do nonsmokers. For some time, tobacco companies and some scientists argued that there was an omitted variable—perhaps failure to exercise or poor diet—that made some people more likely to smoke and more likely to develop lung cancer. If this omitted variable existed, then the finding that smokers were more likely to develop lung cancer would not have been evidence that smoking *caused* lung cancer. In this case, however, nearly all scientists eventually concluded that the omitted variable did not exist and that, in fact, smoking does cause lung cancer.

A related problem in determining cause and effect is known as *reverse causality*. The error of reverse causality occurs when we conclude that changes in variable X cause changes in variable Y when, in fact, it is actually changes in variable Y that cause changes in variable X . For example, panel (b) of Figure 1A.7 plots the number of lawn mowers being used in a neighborhood against the rate at which grass on lawns in the neighborhood is growing. We could conclude from this graph that using lawn mowers *causes* the grass to grow faster. We know, however, that in reality, the causality is in the other direction. Rapidly growing grass during the spring and summer causes the increased use of lawn mowers. Slowly growing grass in the fall or winter or during periods of low rainfall causes the decreased use of lawn mowers.

Once again, in our example, the potential error of reverse causality is obvious. In many economic debates, however, cause and effect can be more difficult to determine.

For example, changes in the money supply, or the total amount of money in the economy, tend to occur at the same time as changes in the total amount of income people in the economy earn. A famous debate in economics was about whether the changes in the money supply caused the changes in total income or whether the changes in total income caused the changes in the money supply. Each side in the debate accused the other side of committing the error of reverse causality. MyEconLab Concept Check

Are Graphs of Economic Relationships Always Straight Lines?

The graphs of relationships between two economic variables that we have drawn so far have been straight lines. The relationship between two variables is *linear* when it can be represented by a straight line. Few economic relationships are actually linear. For example, if we carefully plot data on the price of a product and the quantity demanded at each price, holding constant other variables that affect the quantity demanded, we will usually find a curved—or *nonlinear*—relationship rather than a linear relationship. In practice, however, it is often useful to approximate a nonlinear relationship with a linear relationship. If the relationship is reasonably close to being linear, the analysis is not significantly affected. In addition, it is easier to calculate the slope of a straight line, and it is also easier to calculate the area under a straight line. So, in this textbook, we often assume that the relationship between two economic variables is linear, even when we know that this assumption is not precisely correct. MyEconLab Concept Check

Slopes of Nonlinear Curves

In some situations, we need to take into account the nonlinear nature of an economic relationship. For example, panel (a) of Figure 1A.8 shows the hypothetical relationship between Apple's total cost of producing smartwatches and the quantity of smartwatches produced. The relationship is curved rather than linear. In this case, the cost of production is increasing at an increasing rate, which often happens in manufacturing. In other words, as we move up the curve, its slope becomes larger. (Remember that with a straight line, the slope is always constant.) To see why, first remember that we calculate the slope of a curve by dividing the change in the variable on the y-axis by the change in the variable on the x-axis. As we move from point A to point B, the quantity produced increases by 1 million smartwatches, while the total cost of production increases by \$50 million. Farther up the curve, as we move from point C to point D, the change in quantity is the same—1 million smartwatches—but the change in the total cost of production is now much larger—\$250 million. Because the change in the y variable has increased, while the change in the x variable has remained the same, we know that the slope has increased.

To measure the slope of a nonlinear curve at a particular point, we measure the slope of the line that is tangent to that curve at that point. This tangent line will touch the curve only at that point. We can measure the slope of the tangent line just as we would measure the slope of any other straight line. In panel (b), the tangent line at point B has a slope equal to:

$$\frac{\Delta \text{Cost}}{\Delta \text{Quantity}} = \frac{75}{1} = 75.$$

The tangent line at point C has a slope equal to:

$$\frac{\Delta \text{Cost}}{\Delta \text{Quantity}} = \frac{150}{1} = 150.$$

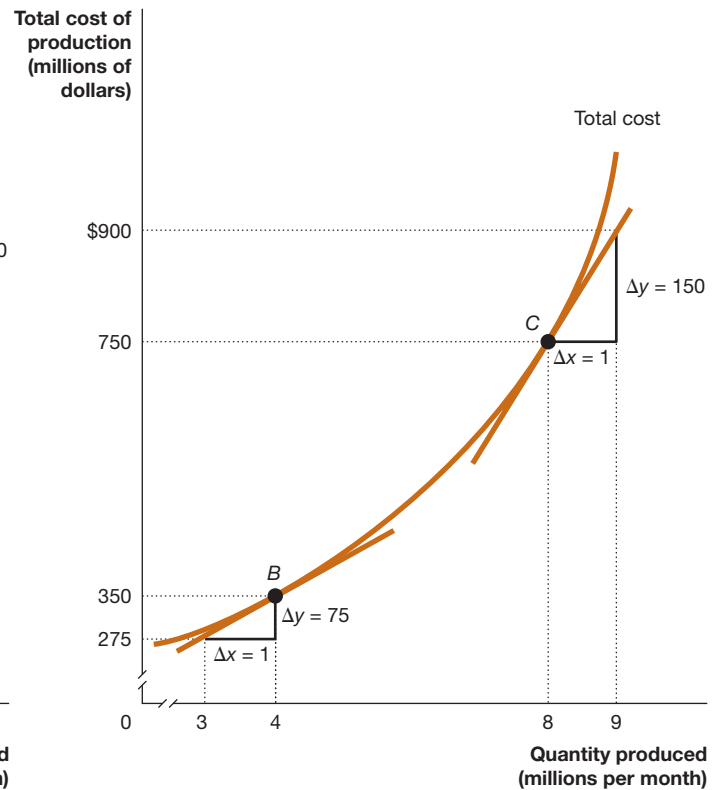

Once again, we see that the slope of the curve is larger at point C than at point B. MyEconLab Concept Check

Formulas

We have just seen that graphs are an important economic tool. In this section, we will review several useful formulas and show how to use them to summarize data and calculate important relationships.

(a) The slope of a nonlinear curve is not constant

(b) The slope of a nonlinear curve is measured by the slope of the tangent line

MyEconLab Animation

Figure 1A.8 The Slope of a Nonlinear Curve

The relationship between the quantity of Apple Watches produced and the total cost of production is curved rather than linear. In panel (a), when we move from point A to point B, the quantity produced increases by 1 million Apple Watches, while the total cost of production increases by \$50 million. Farther up the curve, as we move from point C to point D, the

change in quantity is the same—1 million Apple Watches—but the change in the total cost of production is now much larger—\$250 million.

Because the change in the y variable has increased, while the change in the x variable has remained the same, we know that the slope has increased. In panel (b), we measure the slope of the curve at a particular point by calculating the slope of the tangent line at that point. The slope of the tangent line at point B is 75, and the slope of the tangent line at point C is 150.

Formula for a Percentage Change

The *percentage change* is the change in some economic variable, usually from one period to the next, expressed as a percentage. A key macroeconomic measure is the real gross domestic product (GDP). GDP is the value of all the final goods and services produced in a country during a year. “Real” GDP is corrected for the effects of inflation. When economists say that the U.S. economy grew 2.4 percent during 2014, they mean that real GDP was 2.4 percent higher in 2014 than it was in 2013. The formula for making this calculation is:

$$\left(\frac{\text{GDP}_{2014} - \text{GDP}_{2013}}{\text{GDP}_{2013}} \right) \times 100$$

or, more generally, for any two periods:

$$\text{Percentage change} = \left(\frac{\text{Value in the second period} - \text{Value in the first period}}{\text{Value in the first period}} \right) \times 100.$$

In this case, real GDP was \$15,710 billion in 2013 and \$16,086 billion in 2014. So, the growth rate of the U.S. economy during 2014 was:

$$\left(\frac{\$16,086 - \$15,710}{\$15,710} \right) \times 100 = 2.4\%.$$

Notice that it doesn't matter that in using the formula, we ignored the fact that GDP is measured in billions of dollars. In fact, when calculating percentage changes, *the units don't matter*. The percentage increase from \$15,710 billion to \$16,086 billion is exactly the same as the percentage increase from \$15,710 to \$16,086.

MyEconLab Concept Check

Formulas for the Areas of a Rectangle and a Triangle

Areas that form rectangles and triangles on graphs can have important economic meaning. For example, Figure 1A.9 shows the demand curve for Pepsi. Suppose that the price is currently \$2.00 and that 125,000 bottles of Pepsi are sold at that price. A firm's *total revenue* is equal to the amount it receives from selling its product, or the quantity sold multiplied by the price. In this case, total revenue will equal 125,000 bottles times \$2.00 per bottle, or \$250,000.

The formula for the area of a rectangle is:

$$\text{Area of a rectangle} = \text{Base} \times \text{Height}.$$

In Figure 1A.9, the shaded rectangle also represents the firm's total revenue because its area is given by the base of 125,000 bottles multiplied by the price of \$2.00 per bottle.

We will see in later chapters that areas that are triangles can also have economic significance. The formula for the area of a triangle is:

$$\text{Area of a triangle} = \frac{1}{2} \times \text{Base} \times \text{Height}.$$

The shaded area in Figure 1A.10 is a triangle. The base equals 150,000 – 125,000, or 25,000. Its height equals \$2.00 – \$1.50, or \$0.50. Therefore, its area equals $\frac{1}{2} \times 25,000 \times \0.50 , or \$6,250. Notice that the shaded area is a triangle only if the demand curve is a straight line, or linear. Not all demand curves are linear. However, the formula for the area of a triangle will usually still give a good approximation, even if the demand curve is not linear.

MyEconLab Animation

Figure 1A.10

The Area of a Triangle

The area of a triangle is equal to 1/2 multiplied by its base multiplied by its height. The area of the shaded triangle has a base equal to 150,000 – 125,000, or 25,000, and a height equal to \$2.00 – \$1.50, or \$0.50. Therefore, its area is equal to 1/2 × 25,000 × \$0.50, or \$6,250.

Summary of Using Formulas

You will encounter several other formulas in this book. Whenever you use a formula, you should follow these steps:

1. Make sure you understand the economic concept the formula represents.
2. Make sure you are using the correct formula for the problem you are solving.
3. Make sure the number you calculate using the formula is economically reasonable. For example, if you are using a formula to calculate a firm’s revenue and your answer is a negative number, you know you made a mistake somewhere.

Managers at Tesla Motors Face Trade-offs

Are all-electric cars the wave of the future? If you're like most drivers, you probably like the idea of skipping the gas station in favor of powering up your car by plugging it into an electric outlet. Yet, all-electric cars have struggled to succeed in the marketplace for two key reasons: (1) The lithium batteries that power electric cars are costly, forcing up the prices of the cars, and (2) available batteries need to be recharged every 100 to 300 miles, making the cars impractical for long trips.

Tesla Motors is an American-based automobile manufacturer founded in 2003 by billionaire Elon Musk, who also started the online payment system PayPal and the private space firm SpaceX. Although in 2015 the firm held only a tiny 0.1 percent share of the U.S. car market, it had the goal of becoming the first firm to sell large numbers of all-electric cars. Tesla is building a nationwide network of fast-charging stations to make it easier for drivers to make longer trips. In 2015, its current models had high prices, but it intended to introduce a lower-priced model that would appeal to people who had been buying gasoline-powered cars such as the Toyota Camry or Honda Accord.

Tesla manufactures its cars in Fremont, California. To compete in the automobile market, Tesla's managers must make many strategic decisions, such as whether to introduce new car models. Tesla initially sold only the Model S sedan, with a base price of \$75,000. In late 2015, Tesla introduced a second model, the Model X, a cross between a sport utility

vehicle (SUV) and a minivan. The Model X was designed for families who would otherwise buy traditional gasoline-powered SUVs or minivans. But it also had a very high base price. Ultimately, Tesla's plan to gain a significant share of the automobile market required that it allocate resources to producing an all-electric car priced at about \$35,000.

Tesla's managers must also decide how to sell and service its cars. Tesla has no dealerships. Instead, the company sells its cars only online and relies on company-owned service centers to provide maintenance and repair services. Some economists have questioned whether Tesla will be able to meet its future sales goals without selling cars through dealerships.

Managers also make smaller-scale decisions. For instance, in scheduling production at its Fremont plant, each month Tesla's managers must decide the quantity of Model S sedans and Model X SUVs to manufacture. Like other decisions managers make, this one involves a trade-off: Producing more of one of these two models means producing fewer of the other.

Apple is among a growing list of companies exploring the electric vehicle market. **AN INSIDE LOOK** on page 122 discusses the resources Apple has assembled to produce an electric vehicle as early as 2020.

Economics in Your Life

The Trade-offs When You Buy a Car

When you buy a gasoline-powered car, you probably consider factors such as safety and fuel efficiency. To increase fuel efficiency, automobile manufacturers make some cars that are small and light. Large cars absorb more of the impact of an accident than do small cars, so people are usually safer driving large cars. What do these facts tell us about the relationship between safety and fuel efficiency? Under what circumstances would it be possible for automobile manufacturers to make cars that are both safer and more fuel efficient? As you read the chapter, try to answer these questions. You can check your answers against those provided on **page 120** at the end of this chapter.

Scarcity A situation in which unlimited wants exceed the limited resources available to fulfill those wants.

In a market system, managers are always making decisions like those made by Tesla's managers. These decisions reflect a key fact of economic life: *Scarcity requires trade-offs*. **Scarcity** exists because we have unlimited wants but only limited resources available to fulfill those wants. Goods and services are scarce. So, too, are the economic resources, or *factors of production*—workers, capital, natural resources, and entrepreneurial ability—used to make goods and services. Your time is scarce, which means you face trade-offs: If you spend an hour studying for an economics exam, you have one less hour to spend studying for a psychology exam or going to the movies. If your university decides to use some of its scarce budget to buy new computers for the computer labs, those funds will not be available to buy new books for the library or to resurface the student parking lots. If Tesla decides to devote some of the scarce workers and machinery in its Fremont assembly plant to producing more Model X SUVs, those resources will not be available to produce more Model S sedans.

Households and firms make many of their decisions in markets. Trade is a key activity that takes place in markets. Trade results from the decisions of millions of households and firms around the world. By engaging in trade, people can raise their incomes. In this chapter, we provide an overview of how the market system coordinates the independent decisions of these millions of households and firms. We begin our analysis of the economic consequences of scarcity and how a market system works by introducing an important economic model: the *production possibilities frontier*.

2.1

Production Possibilities Frontiers and Opportunity Costs

LEARNING OBJECTIVE: Use a production possibilities frontier to analyze opportunity costs and trade-offs.

As we saw in the chapter opener, Tesla operates an automobile factory in Fremont, California, where it assembles two car models. Because the firm's resources—workers, machinery, materials, and entrepreneurial ability—are limited, Tesla faces a trade-off: Resources devoted to producing one model are not available for producing the other model. Chapter 1 explained that economic models can be useful in analyzing many questions. We can use a simple model called the *production possibilities frontier* to analyze the trade-offs Tesla faces in its Fremont plant. A **production possibilities frontier (PPF)** is a curve showing the maximum attainable combinations of two goods that can be produced with available resources and current technology. In Tesla's case, the company produces only Model S sedans and Model X SUVs at the Fremont plant, using workers, materials, robots, and other machinery.

Production possibilities frontier (PPF) A curve showing the maximum attainable combinations of two goods that can be produced with available resources and current technology.

Graphing the Production Possibilities Frontier

Figure 2.1 uses a production possibilities frontier to illustrate the trade-offs that Tesla faces. The numbers from the table are plotted in the graph. The line in the graph represents Tesla's production possibilities frontier. If Tesla uses all its resources to produce Model S sedans, it can produce 80 per day—point A at one end of the production possibilities frontier. If Tesla uses all its resources to produce Model X SUVs, it can produce 80 per day—point E at the other end of the production possibilities frontier. If Tesla devotes resources to producing both vehicles, it could be at a point like B, where it produces 60 sedans and 20 SUVs.

All the combinations either on the frontier—like points A, B, C, D, and E—or inside the frontier—like point F—are *attainable* with the resources available. Combinations on the frontier are *efficient* because all available resources are being fully

D	20	60
E	0	80

MyEconLab Animation

Figure 2.1

Tesla's Production Possibilities Frontier

Tesla faces a trade-off: To build one more sedan, it must build one fewer SUV. The production possibilities frontier illustrates the trade-off Tesla faces. Combinations on the production possibilities frontier—like points A, B, C, D, and E—are *efficient* because the maximum output is being obtained from the available resources. Combinations inside the frontier—like point F—are *inefficient* because some resources are not being used. Combinations outside the frontier—like point G—are *unattainable* with current resources.

utilized, and the fewest possible resources are being used to produce a given amount of output. Combinations inside the frontier—like point F—are *inefficient* because maximum output is not being obtained from the available resources—perhaps because the assembly line is not operating at its capacity. Tesla might like to be beyond the frontier—at a point like G, where it would be producing 60 sedans and 50 SUVs per day—but points beyond the production possibilities frontier are *unattainable*, given the firm's current resources. To produce the combination at G, Tesla would need more machines and more workers.

Notice that if Tesla is producing efficiently and is on the production possibilities frontier, the only way to produce more of one vehicle is to produce fewer of the other vehicle. Recall from Chapter 1 that the **opportunity cost** of any activity is the highest-valued alternative that must be given up to engage in that activity. For Tesla, the opportunity cost of producing one more SUV is the number of sedans the company will not be able to produce because it has shifted those resources to producing the SUV. For example, if Tesla moves from point B to point C, the opportunity cost of producing 20 more SUVs per day is the 20 fewer sedans that it can produce.

What point on the production possibilities frontier is best? We can't tell without further information. If consumer demand for SUVs is greater than the demand for sedans, the company is likely to choose a point closer to E. If demand for sedans is greater than the demand for SUVs, the company is likely to choose a point closer to A.

Solved Problem 2.1

MyEconLab Interactive Animation

Drawing a Production Possibilities Frontier for Tesla Motors

Suppose, for simplicity, that during any given week, the machinery and number of workers at Tesla Motors's Fremont plant cannot be increased. So the number of sedans or SUVs the company can produce during the week depends on how many hours are devoted to assembling each of the different models. Assume that SUVs are more difficult to assemble, so if Tesla devotes an hour to assembling sedans, it will produce 15 vehicles, but if Tesla devotes an hour to producing SUVs, it will produce only 10 vehicles. Assume that the plant can run for 8 hours per day.

- a. Use the information given to fill in the missing cells in the following table:

Choice	Hours Spent Making		Quantity Produced per Day	
	Sedans	SUVs	Sedans	SUVs
A	8	0		
B	7	1		
C	6	2		
D	5	3		
E	4	4		
F	3	5		
G	2	6		
H	1	7		
I	0	8		

- b. Use the data in the table to draw a production possibilities frontier graph illustrating Tesla's trade-off between assembling sedans and assembling SUVs. Label the vertical axis "Quantity of sedans produced per day." Label the horizontal axis "Quantity of SUVs produced per day." Make sure to label the values where Tesla's production possibilities frontier intersects the vertical and horizontal axes.
- c. Label the points representing choice D and choice E. If Tesla is at choice D, what is its opportunity cost of making 10 more SUVs?

Solving the Problem

Step 1: Review the chapter material. This problem is about using production possibilities frontiers to analyze trade-offs, so you may want to review the section "Graphing the Production Possibilities Frontier," which begins on page 100.

Step 2: Answer part (a) by filling in the table. If Tesla can assemble 15 sedans in 1 hour, then with choice A, it can assemble 120 sedans and 0 SUVs. Because Tesla can assemble 10 SUVs in 1 hour, with choice B, it will produce 105 sedans and 10 SUVs. Using similar reasoning, you can fill in the remaining cells in the table as follows:

Choice	Hours Spent Making		Quantity Produced per Day	
	Sedans	SUVs	Sedans	SUVs
A	8	0	120	0
B	7	1	105	10
C	6	2	90	20
D	5	3	75	30
E	4	4	60	40
F	3	5	45	50
G	2	6	30	60
H	1	7	15	70
I	0	8	0	80

Step 3: Answer part (b) by drawing the production possibilities frontier graph. Using the data in the table in step 2, you should draw a graph that looks like this:

If Tesla devotes all 8 hours to assembling sedans, it will produce 120 sedans. Therefore, Tesla's production possibilities frontier will intersect the vertical axis at 120 sedans produced. If Tesla devotes all 8 hours to assembling SUVs, it will produce 80 SUVs. Therefore, Tesla's production possibilities frontier will intersect the horizontal axis at 80 SUVs produced.

Step 4: Answer part (c) by labeling choices D and E on your graph. The points for choices D and E can be plotted using the information from the table:

Moving from choice D to choice E increases Tesla's production of SUVs by 10 but lowers its production of sedans by 15. Therefore, Tesla's opportunity cost of producing 10 more SUVs is making 15 fewer sedans.

Your Turn: For more practice, do related problem 1.10 on page 125 at the end of this chapter.

MyEconLab Study Plan

Increasing Marginal Opportunity Costs

We can use the production possibilities frontier to explore issues concerning the economy as a whole. Suppose we divide all the goods and services produced in the economy into just two types: military goods and civilian goods. In Figure 2.2, we let tanks represent military goods and automobiles represent civilian goods. If all the country's resources are devoted to producing military goods, 400 tanks can be produced in one year. If all resources are devoted to producing civilian goods, 500 automobiles can be produced in one year. Devoting resources to producing both goods results in the economy being at other points along the production possibilities frontier.

Notice that this production possibilities frontier is bowed outward rather than being a straight line. Because the curve is bowed out, the opportunity cost of automobiles in terms of tanks depends on where the economy currently is on the production possibilities frontier. For example, to increase automobile production from 0 to 200—moving from point A to point B—the economy has to give up only 50 tanks. But to increase automobile production by another 200 vehicles—moving from point B to point C—the economy has to give up 150 tanks.

As the economy moves down the production possibilities frontier, it experiences *increasing marginal opportunity costs* because increasing automobile production by a given quantity requires larger and larger decreases in tank production. Increasing marginal opportunity costs occur because some workers, machines, and other resources are better suited to one use than to another. At point A, some resources that are well suited to producing automobiles are forced to produce tanks. Shifting these resources into producing automobiles by moving from point A to point B allows a substantial increase in automobile production, without much loss of tank production. But as the economy moves down the production possibilities frontier, more and more resources that are better suited to tank production are switched to automobile production. As a result, the increases in automobile production become increasingly smaller, while the decreases in tank production become increasingly larger. We would expect in most situations that production possibilities frontiers will be bowed outward rather than linear, as in the Tesla example discussed earlier.

The idea of increasing marginal opportunity costs illustrates an important economic concept: *The more resources already devoted to an activity, the smaller the payoff to devoting additional resources to that activity.* For example:

- The more hours you have already spent studying economics, the smaller the increase in your test grade from each additional hour you spend—and the greater the opportunity cost of using the hour in that way.

MyEconLab Animation

Figure 2.2

Increasing Marginal Opportunity Costs

As the economy moves down the production possibilities frontier, it experiences *increasing marginal opportunity costs* because increasing automobile production by a given quantity requires larger and larger decreases in tank production. For example, to increase automobile production from 0 to 200—moving from point A to point B—the economy has to give up only 50 tanks. But to increase automobile production by another 200 vehicles—moving from point B to point C—the economy has to give up 150 tanks.

- The more funds a firm has devoted to research and development during a given year, the smaller the amount of useful knowledge it receives from each additional dollar spent—and the greater the opportunity cost of using the funds in that way.
- The more funds the federal government spends cleaning up the environment during a given year, the smaller the reduction in pollution from each additional dollar spent—and, once again, the greater the opportunity cost of using the funds in that way.

MyEconLab [Concept Check](#)

Economic Growth

At any given time, the total resources available to any economy are fixed. So, for example, if the United States produces more automobiles, it must produce less of something else—tanks in our example. The capital stock is the amount of machinery and other physical capital available in an economy. Over time, the resources available to an economy may increase because both the labor force and the capital stock increase. When the amount of resources increases, the economy's production possibilities frontier shifts outward, making it possible to produce both more automobiles and more tanks. Panel (a) of Figure 2.3 shows that over time the economy can move from point A to point B, producing more tanks and more automobiles.

Similarly, technological change makes it possible to produce more goods with the same number of workers and the same amount of machinery, which also shifts the production possibilities frontier outward. Technological change need not affect all sectors equally. Panel (b) of Figure 2.3 shows the results of technological change in the automobile industry that increases the quantity of automobiles workers can produce per year while leaving unchanged the quantity of tanks they can produce.

Outward shifts in the production possibilities frontier represent **economic growth** because they allow the economy to increase the production of goods and services, which ultimately raises the standard of living. In the United States and other high-income countries, the market system has aided the process of economic growth, which over the past 200 years has greatly increased the well-being of the average person.

the quantity of vehicles workers can produce per year while leaving unchanged the maximum quantity of tanks they can produce. Outward shifts in the production possibilities frontier represent *economic growth*.

2.2 Comparative Advantage and Trade

LEARNING OBJECTIVE: Describe comparative advantage and explain how it serves as the basis for trade.

Trade The act of buying and selling.

We can use the concepts of the production possibilities frontier and opportunity cost to understand the basic economic activity of *trade*. Markets are fundamentally about **trade**, which is the act of buying and selling. Sometimes we trade directly, as when children trade one baseball card for another baseball card. But often we trade indirectly: We sell our labor services as, say, an accountant, a salesperson, or a nurse for money, and then we use the money earned to buy goods and services. Although in these cases trade takes place indirectly, ultimately the accountant, salesperson, or nurse is trading his or her services for food, clothing, and other goods and services. One of the great benefits of trade is that it makes it possible for people to become better off by increasing both their production and their consumption.

Specialization and Gains from Trade

Consider the following situation: You and your neighbor both have fruit trees on your properties. Initially, suppose you have only apple trees and your neighbor has only cherry trees. In this situation, if you both like apples and cherries, there is an obvious opportunity for both of you to gain from trade: You trade some of your apples for some of your neighbor's cherries, making you both better off. But what if there are apple and cherry trees growing on both of your properties? In that case, there can still be gains from trade. For example, your neighbor might be very good at picking apples, and you might be very good at picking cherries. It would make sense for your neighbor to concentrate on picking apples and for you to concentrate on picking cherries. You can then trade some of the cherries you pick for some of the apples your neighbor picks. But what if your neighbor is actually better at picking both apples and cherries than you are?

We can use production possibilities frontiers (PPFs) to show how your neighbor can benefit from trading with you *even though she is better than you are at picking both apples and cherries*. (For simplicity, and because it will not have any effect on the conclusions we draw, we will assume that the PPFs in this example are straight lines.) The table in Figure 2.4 shows how many apples and how many cherries you and your neighbor can pick in one week. The graph in the figure uses the data from the table to construct PPFs. Panel (a) shows your PPF. If you devote all your time to picking apples, you can pick 20 pounds of apples per week. If you devote all your time to picking cherries, you can pick 20 pounds per week. Panel (b) shows that if your neighbor devotes all her time to picking apples, she can pick 30 pounds. If she devotes all her time to picking cherries, she can pick 60 pounds.

The PPFs in Figure 2.4 show how many apples and cherries you and your neighbor can consume *without trade*. Suppose that when you don't trade with your neighbor, you pick and consume 8 pounds of apples and 12 pounds of cherries per week. This combination of apples and cherries is represented by point A in panel (a) of Figure 2.5. When your neighbor doesn't trade with you, she picks and consumes 9 pounds of apples and 42 pounds of cherries per week. This combination of apples and cherries is represented by point C in panel (b).

After years in which you each pick and consume your own apples and cherries, suppose your neighbor comes to you one day with the following proposal: Next week she will trade you 15 pounds of her cherries for 10 pounds of your apples. Should you accept this proposal? As we can show in Figure 2.5, you should accept because you will end up with more apples and more cherries to consume. To take advantage of her proposal, you should specialize in picking only apples rather than splitting your time between picking apples and picking cherries. We know specializing will allow you to pick 20 pounds of apples. You can trade 10 pounds of apples to your neighbor for 15 pounds of her cherries. The result is that you will be able to consume 10 pounds of

When your neighbor doesn't trade with you, she picks and consumes 9 pounds of apples and 42 pounds of cherries per week—point C in panel (b). If you specialize in picking apples, you can pick 20 pounds. If your neighbor specializes in picking cherries, she can pick 60 pounds. If you trade 10 pounds

of your apples for 15 pounds of your neighbor's cherries, you will be able to consume 10 pounds of apples and 15 pounds of cherries—point B in panel (a). Your neighbor can now consume 10 pounds of apples and 45 pounds of cherries—point D in panel (b). You and your neighbor are both better off as a result of the trade.

apples and 15 pounds of cherries (point *B* in panel (a) of Figure 2.5). You are clearly better off as a result of trading with your neighbor: You can now consume 2 more pounds of apples and 3 more pounds of cherries than you were consuming without trading. You have moved beyond your *PPF*!

Your neighbor has also benefited from the trade. By specializing in picking only cherries, she can pick 60 pounds. She trades 15 pounds of cherries to you for 10 pounds of apples. She can then consume 10 pounds of apples and 45 pounds of cherries (point *D* in panel (b) of Figure 2.5). This combination is 1 more pound of apples and 3 more pounds of cherries than she was consuming before trading with you. She also has moved beyond her *PPF*. Table 2.1 summarizes the changes in production and consumption that result from your trade with your neighbor. (In this example, we chose one specific rate of trading cherries for apples—15 pounds of cherries for 10 pounds of apples. There are, however, many other rates of trading cherries for apples that would also make you and your neighbor better off.)

MyEconLab **Concept Check**

Absolute advantage The ability of an individual, a firm, or a country to produce more of a good or service than competitors, using the same amount of resources.

Absolute Advantage versus Comparative Advantage

Perhaps the most remarkable aspect of the preceding example is that your neighbor benefits from trading with you even though she is better than you at picking both apples and cherries. **Absolute advantage** is the ability of an individual, a firm, or a country to produce more of a good or service than competitors, using the same amount of resources. Your neighbor has an absolute advantage over you in picking both apples and cherries because she can pick more of each fruit than you can in the same amount of time. Although it seems that your neighbor should pick her own apples *and* her own cherries, we have just seen that she is better off specializing in picking cherries and leaving picking apples to you.

We can consider further why both you and your neighbor benefit from specializing in picking only one fruit. First, think about the opportunity cost to each of you of picking the two fruits. We saw from the *PPF* in Figure 2.4 that if you devoted all your time to picking apples, you would be able to pick 20 pounds of apples per week. As you move down your *PPF* and shift time away from picking apples to picking cherries, you have to give up 1 pound of apples for each pound of cherries you pick (the slope of your *PPF* is -1). (For a review of calculating slopes, see the appendix to Chapter 1.) Therefore, your opportunity cost of picking 1 pound of cherries is 1 pound of apples. By the same reasoning, your opportunity cost of picking 1 pound of apples is 1 pound of cherries. Your neighbor's *PPF* has a different slope, so she faces a different trade-off: As she shifts time from picking apples to picking cherries, she has to give up 0.5 pound of apples for every 1 pound of cherries she picks (the slope of your neighbor's *PPF* is -0.5). As she shifts time from picking cherries to picking apples, she gives up 2 pounds of cherries for every 1 pound of apples she picks. Therefore, her opportunity cost of picking 1 pound of apples is 2 pounds of cherries, and her opportunity cost of picking 1 pound of cherries is 0.5 pound of apples.

	Opportunity Cost of Picking 1 Pound of Apples	Opportunity Cost of Picking 1 Pound of Cherries
You	1 pound of cherries	1 pound of apples
Your Neighbor	2 pounds of cherries	0.5 pound of apples

MyEconLab Study Plan

Table 2.2

Opportunity Costs of Picking Apples and Cherries

Table 2.2 summarizes the opportunity costs for you and your neighbor of picking apples and cherries. Note that even though your neighbor can pick more apples in a week than you can, the *opportunity cost* of picking apples is higher for her than for you because when she picks apples, she gives up more cherries than you do. So, even though she has an absolute advantage over you in picking apples, it is more costly for her to pick apples than it is for you. The table also shows that her opportunity cost of picking cherries is lower than yours. **Comparative advantage** is the ability of an individual, a firm, or a country to produce a good or service at a lower opportunity cost than competitors. In picking apples, your neighbor has an *absolute advantage* over you, while you have a *comparative advantage* over her. Your neighbor has both an absolute advantage and a comparative advantage over you in picking cherries. As we have seen, you are better off specializing in picking apples, and your neighbor is better off specializing in picking cherries.

MyEconLab Concept Check

Comparative advantage The ability of an individual, a firm, or a country to produce a good or service at a lower opportunity cost than competitors.

Comparative Advantage and the Gains from Trade

We have just arrived at an important economic principle: *The basis for trade is comparative advantage, not absolute advantage.* The fastest apple pickers do not necessarily do much apple picking. If the fastest apple pickers have a comparative advantage in some other activity—picking cherries, playing Major League Baseball, or being industrial engineers—they are better off specializing in that activity. Individuals, firms, and countries are better off if they specialize in producing goods and services for which they have a comparative advantage and obtain the other goods and services they need by trading. We will return to the important concept of comparative advantage in Chapter 9, which is devoted to the subject of international trade.

MyEconLab Concept Check

Don't Let This Happen to You

Don't Confuse Absolute Advantage and Comparative Advantage

First, make sure you know the definitions:

- **Absolute advantage.** The ability of an individual, a firm, or a country to produce more of a good or service than competitors, using the same amount of resources. In our example, your neighbor has an absolute advantage over you in both picking apples and picking cherries.
- **Comparative advantage.** The ability of an individual, a firm, or a country to produce a good or service at a lower opportunity cost than competitors. In our example, your neighbor has a comparative advantage in picking cherries, but you have a comparative advantage in picking apples.

Keep these two key points in mind:

1. It is possible to have an absolute advantage in producing a good or service without having a comparative advantage. This is the case with your neighbor picking apples.
2. It is possible to have a comparative advantage in producing a good or service without having an absolute advantage. This is the case with your picking apples.

Solved Problem 2.2

MyEconLab Interactive Animation

Comparative Advantage and the Gains from Trade

Suppose that Canada and the United States both produce maple syrup and honey, which are sold for the same price in both countries. These are the combinations of the two goods that each country can produce in one day, using the same amounts of capital and labor:

Canada		United States	
Honey (in tons)	Maple Syrup (in tons)	Honey (in tons)	Maple Syrup (in tons)
0	60	0	50
10	45	10	40
20	30	20	30
30	15	30	20
40	0	40	10
		50	0

- Which country has a comparative advantage in producing maple syrup? Which country has a comparative advantage in producing honey?
- Suppose that Canada is currently producing 30 tons of honey and 15 tons of maple syrup, and the United States is currently producing 10 tons of honey and 40 tons of maple syrup. Demonstrate that Canada and the United States can both be better off if they specialize in producing only one good and trade for the other.
- Illustrate your answer to part (b) by drawing a *PPF* for the United States and a *PPF* for Canada. Show on your *PPFs* the combinations of honey and maple syrup produced and consumed in each country before and after trade.

Solving the Problem

Step 1: Review the chapter material. This problem is about comparative advantage, so you may want to review the section “Absolute Advantage versus Comparative Advantage,” which begins on page 108.

Step 2: Answer part (a) by calculating which country has a comparative advantage in each activity. Remember that a country has a comparative advantage in producing a good if it can produce the good at the lowest opportunity cost. When Canada produces 1 more ton of honey, it produces 1.5 tons less of maple syrup. When the United States produces 1 more ton of honey, it produces 1 ton less of maple syrup. Therefore, for the United States, the opportunity cost of producing honey—1 ton of maple syrup—is lower than for Canada—1.5 tons of maple syrup. When Canada produces 1 more ton of maple syrup, it produces 0.67 ton less of honey. When the United States produces 1 more ton of maple syrup, it produces 1 ton less of honey. Therefore, Canada’s opportunity cost of producing maple syrup—0.67 ton of honey—is lower than that of the United States—1 ton of honey. We can conclude that the United States has a comparative advantage in the production of honey and Canada has a comparative advantage in the production of maple syrup.

Step 3: Answer part (b) by showing that specialization makes Canada and the United States better off. We know that Canada and the United States should each specialize where it has a comparative advantage. If both countries specialize, Canada will produce 60 tons of maple syrup and 0 tons of honey, and the United States will produce 0 tons of maple syrup and 50 tons of honey. After both countries specialize, the United States could then trade 30 tons of honey to Canada for 40 tons of maple syrup. (Other mutually beneficial trades are possible as well.) We can summarize the results in a table:

	Before Trade		After Trade	
	Honey (in tons)	Maple Syrup (in tons)	Honey (in tons)	Maple Syrup (in tons)
Canada	30	15	30	20
United States	10	40	20	40

The United States is better off after trade because it can consume the same amount of maple syrup and 10 more tons of honey. Canada is better off after trade because it can consume the same amount of honey and 5 more tons of maple syrup.

Step 4: Answer part (c) by drawing the PPFs.

Making the Connection

MyEconLab Video

Comparative Advantage, Opportunity Cost, and Housework

Among roommates, married couples, and other people living together, dividing up the household chores can be a source of stress. Traditionally among married couples, women did most of the housework, such as preparing meals, cleaning, and doing laundry. In 1965, married women with children averaged about 32 hours of housework per week, while married men averaged only 4 hours. Today, women average about 15 hours of housework, while men average about 10 hours.

Housework doesn't seem to be part of buying, selling, and the usual topics of business and economics. In fact, we can use basic economic concepts to analyze housework. Consider first the most efficient way to divide up household chores. Suppose Jack and Jill need to decide how they will get the cooking and laundry done. Assume that Jack has an absolute advantage over Jill in both chores, but he has a big advantage over Jill in cooking—he takes much less time to prepare very tasty meals—but is only a little faster than Jill in doing laundry. In other words, assuming that they have the same amount of time available to do housework, Jack has a comparative advantage in cooking, while Jill has a comparative advantage in doing laundry. So rather than Jack and Jill both doing some of the cooking and some of the laundry, they would be better off if Jack follows his comparative advantage and does all the cooking, while Jill follows her comparative advantage and does all the laundry.

Economics can also provide some insight into the decline in the number of hours spent on housework since the 1960s. Combined, men and women now spend more than 30 percent fewer hours on housework. This decline has been partly driven by technology, particularly improvements in household appliances, such as dishwashers and microwave ovens. The decline in the number of hours women devote to housework also reflects the greater job opportunities available to women today compared with the 1960s. The opportunity cost to a woman of spending time on housework and childcare is the wage she gives up by not spending that time in paid work. If a woman could work for an hour at a wage of \$20 but spends that hour doing household chores, the opportunity cost of the time spent on chores is \$20. As job opportunities for women and the wages those jobs pay have increased, so has the opportunity cost of doing housework. So in addition to taking advantage of improved appliances, many families have found

What's the most efficient way to divide up household chores?

that the cost of hiring specialists in household chores, such as cleaning services and lawn care services, is lower than the cost of the wife (or husband) performing those chores.

As women's wages have risen relative to men's wages, the opportunity cost to women of doing housework has increased more than has the opportunity cost to men. So we would expect that in addition to women devoting fewer hours to housework, the gap between the hours women and men devote would narrow. In fact, while in 1965, women devoted 28 more hours to housework than did men, in 2014, they devoted only 5 more hours. The average number of hours women devoted to paid work increased from 8 hours per week to 19 hours.

Of course, changes in social attitudes also help explain changes in how men and women allocate their time. But we have seen that the basic economic concepts of comparative advantage and opportunity cost provide important insights into the not-so-wonderful world of household chores.

2.3 The Market System

LEARNING OBJECTIVE: Explain the basics of how a market system works.

We have seen that households, firms, and the government face trade-offs and incur opportunity costs because resources are scarce. We have also seen that trade allows people to specialize according to their comparative advantage. By engaging in trade, people can raise their incomes and their standard of living. Of course, trade in the modern world is much more complex than the examples we have considered so far. Trade today involves the decisions of millions of people around the world. How are the decisions of these millions of people coordinated? In the United States and most other countries, trade is carried out in markets. Markets also determine the answers to the three fundamental questions discussed in Chapter 1:

1. What goods and services will be produced?
2. How will the goods and services be produced?
3. Who will receive the goods and services produced?

Recall that a **market** is a group of buyers and sellers of a good or service and the institution or arrangement by which they come together to trade. Markets take many forms: They can be physical places, such as the pizza parlors in your city or the New York Stock Exchange, or virtual places, such as eBay. In a market, the buyers are demanders of goods or services, and the sellers are suppliers of goods or services. Households and firms interact in two types of markets: *product markets* and *factor markets*. **Product markets** are markets for goods—such as computers—and services—such as medical treatment. In product markets, households are demanders and firms are suppliers. **Factor markets** are markets for the *factors of production*. **Factors of production** are the inputs used to make goods and services. Factors of production are divided into four broad categories:

1. *Labor* includes all types of work, from the part-time labor of teenagers working at McDonald's to the work of senior managers in large corporations.
2. *Capital* refers to physical capital, such as computers and machine tools, that is used to produce other goods.
3. *Natural resources* include land, water, oil, iron ore, and other raw materials (or "gifts of nature") that are used in producing goods.

Market A group of buyers and sellers of a good or service and the institution or arrangement by which they come together to trade.

Product market A market for goods—such as computers—or services—such as medical treatment.

Factor market A market for the factors of production, such as labor, capital, natural resources, and entrepreneurial ability.

Factors of production Labor, capital, natural resources, and other inputs used to make goods and services.

4. An *entrepreneur* is someone who operates a business. *Entrepreneurial ability* is the ability to bring together the other factors of production to successfully produce and sell goods and services.

The Circular Flow of Income

Two key groups participate in markets:

1. *Households* are all the individuals in a home. Households are suppliers of factors of production—particularly labor—employed by firms to make goods and services. Households use the income they receive from selling the factors of production to purchase the goods and services supplied by firms. We are familiar with households as suppliers of labor because most people earn most of their income by going to work, meaning they are selling their labor services to firms in the labor market. But households own the other factors of production as well, either directly or indirectly, by owning the firms that own these resources. All firms are owned by households. Small firms, like a neighborhood restaurant, might be owned by one person. Large firms, like Apple, are owned by millions of households that buy shares of stock in them. When firms pay profits to the people who own them, the firms are paying for using the capital and natural resources that are supplied to them by those owners. So, we can generalize by saying that in factor markets, households are suppliers and firms are demanders.
2. *Firms* are suppliers of goods and services. Firms use the funds they receive from selling goods and services to buy or hire the factors of production needed to make the goods and services.

We can use a simple economic model called the **circular-flow diagram** to see how participants in markets are linked. Figure 2.6 shows that in factor markets, households supply labor and other factors of production in exchange for wages and other

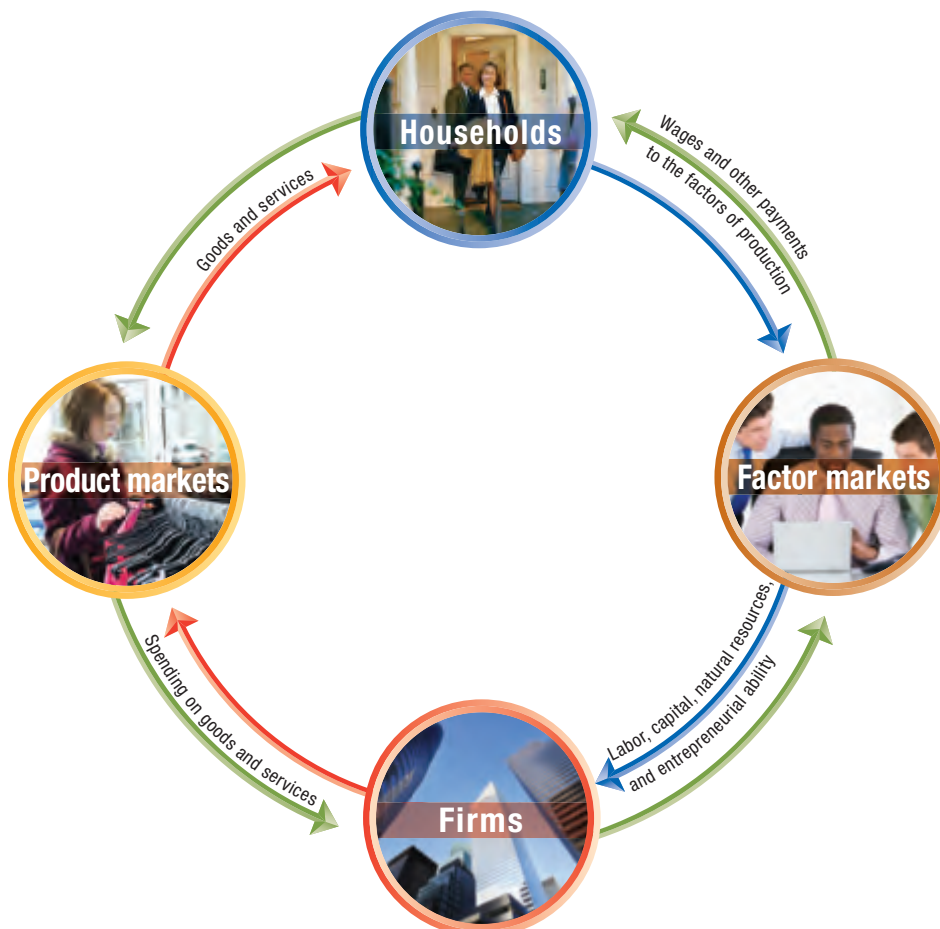

Circular-flow diagram A model that illustrates how participants in markets are linked.

MyEconLab Animation

Figure 2.6

The Circular-Flow Diagram

Households and firms are linked together in a circular flow of production, income, and spending. The blue arrows show the flow of the factors of production. In factor markets, households supply labor, entrepreneurial ability, and other factors of production to firms. Firms use these factors of production to make goods and services that they supply to households in product markets. The red arrows show the flow of goods and services from firms to households. The green arrows show the flow of funds. In factor markets, households receive wages and other payments from firms in exchange for supplying the factors of production. Households use these wages and other payments to purchase goods and services from firms in product markets. Firms sell goods and services to households in product markets, and they use the funds to purchase the factors of production from households in factor markets.

payments from firms. In product markets, households use the payments they earn in factor markets to purchase the goods and services supplied by firms. Firms produce these goods and services using the factors of production supplied by households. In the figure, the blue arrows show the flow of factors of production from households through factor markets to firms. The red arrows show the flow of goods and services from firms through product markets to households. The green arrows show the flow of funds from firms through factor markets to households and the flow of spending from households through product markets to firms.

Like all economic models, the circular-flow diagram is a simplified version of reality. Figure 2.6 leaves out the important role of government in buying goods from firms and in making payments, such as Social Security or unemployment insurance payments, to households. The figure also leaves out the roles played by banks, the stock and bond markets, and other parts of the *financial system* in aiding the flow of funds from lenders to borrowers. Finally, the figure does not show that some goods and services purchased by domestic households are produced in foreign countries and some goods and services produced by domestic firms are sold to foreign households. (We explore the government, the financial system, and the international sector further in later chapters.) Despite these simplifications, the circular-flow diagram in Figure 2.6 is useful for seeing how product markets, factor markets, and their participants are linked together. One of the great wonders of the market system is that it manages to successfully coordinate the independent activities of so many households and firms.

MyEconLab **Concept Check**

Free market A market with few government restrictions on how a good or service can be produced or sold or on how a factor of production can be employed.

The Gains from Free Markets

A **free market** exists when the government places few restrictions on how goods and services can be produced or sold or on how factors of production can be employed. Governments in all modern economies intervene more than is consistent with a fully free market. In that sense, we can think of the free market as being a benchmark against which we can judge actual economies. There are relatively few government restrictions on economic activities in the United States, Canada, Western Europe, Hong Kong, Singapore, and Estonia. So these countries come close to the free market benchmark. In countries such as Cuba and North Korea, the free market system has been rejected in favor of centrally planned economies with extensive government control over product and factor markets. Countries that come closest to the free market benchmark have been more successful than countries with centrally planned economies in providing their people with rising living standards.

The Scottish philosopher Adam Smith is considered the father of modern economics because his book, *An Inquiry into the Nature and Causes of the Wealth of Nations*, published in 1776, was an early and very influential argument for the free market system. Smith was writing at a time when extensive government restrictions on markets were common. In many parts of Europe, the *guild system* prevailed. Under this system, governments would give guilds, or organizations of producers, the authority to control the production of a good. For example, the shoemakers' guild controlled who was allowed to produce shoes, how many shoes they could produce, and what price they could charge. In France, the cloth makers' guild even dictated the number of threads in the weave of the cloth.

Smith argued that such restrictions reduced the income and wealth of a country and its people by restricting the quantity of goods produced. Some people at the time supported the restrictions of the guild system because it was in their financial interest to do so. If you were a member of a guild, the restrictions served to reduce the competition you faced. But other people sincerely believed that the alternative to the guild system was economic disorder. Smith argued that these people were wrong and that a country could enjoy a smoothly functioning economic system if firms were freed from guild restrictions.

MyEconLab **Concept Check**

The Market Mechanism

In Smith's day, defenders of the guild system argued that if the shoemakers' guild did not control shoe production, either too many or too few shoes would be produced.

In contrast, Smith maintained that prices would do a better job of coordinating the activities of buyers and sellers than the guilds could. A key to understanding Smith's argument is the assumption that *individuals usually act in a rational, self-interested way*. In particular, individuals take those actions that are most likely to make themselves better off financially. This assumption of rational, self-interested behavior underlies nearly all economic analysis. In fact, economics can be distinguished from other disciplines that study human behavior—such as sociology and psychology—by its emphasis on the assumption of self-interested behavior. Adam Smith understood—as economists today understand—that people's motives can be complex. But when we analyze people in the act of buying and selling, the motivation of financial reward usually provides the best explanation for the actions people take.

For example, suppose that a significant number of consumers switch from buying regular gasoline-powered cars to buying gasoline/electric-powered hybrid cars, such as the Toyota Prius, or all-electric cars, such as the Tesla Model S. Firms will find that they can charge relatively higher prices for hybrid cars and electric cars than they can for gasoline-powered cars. The self-interest of these firms will lead them to respond to consumers' wishes by producing more hybrid and electric cars and fewer gasoline-powered cars. Or suppose that consumers decide that they want to eat less bread, pasta, and other foods that are high in carbohydrates. Then the prices firms can charge for bread and pasta will fall. The self-interest of firms will lead them to produce less bread and pasta, which, in fact, is what has happened over the past 10 years.

Note that for the market mechanism to work in response to changes in consumers' wants, *prices must be flexible*. The *relative price* is the price of one good or service relative to the prices of other goods or services. Changes in relative prices provide information, or a signal, to both consumers and firms. For example, consumers worldwide have increased their demand for cattle and poultry. Because corn is fed to cattle and poultry, prices for corn have increased relative to prices for other crops. Many farmers in the United States received this price signal and responded by increasing the amount of corn they planted and decreasing the amount of soybeans and wheat. One Kansas farmer was quoted as saying, "It seemed to me there was \$100 to \$150 per acre more money in the corn than there was in the beans. That's the kind of math that a lot of guys were using." In recent years, the United States has experienced record corn crops. Similarly, falling prices for DVDs and music CDs in the 2000s were a signal to movie studios and record companies to devote fewer resources to these products and more resources to making movies and music available online.

In the United States today, governments at the federal, state, and local levels set or regulate the prices of only about 10 to 20 percent of goods and services. The prices of other goods and services are free to change as consumer wants change and as costs of production change.

In the case where consumers want more of a product, and in the case where they want less of a product, the market system responds without a guild or the government giving orders about how much to produce or what price to charge. Economists have used Adam Smith's metaphor of the *invisible hand* to describe how the market leads firms to provide consumers with the goods they want. Firms respond *individually* to changes in prices by making decisions that *collectively* end up satisfying the wants of consumers.

components into a finished product. Far from being produced entirely by one company in one country, the iPad requires the coordinated activities of thousands of workers and dozens of firms spread around the world.

Foxconn, which is based in Taiwan, assembles the iPad in factories in Shenzhen and Chengdu, China, and Jundiai, São Paulo, Brazil, and ships them to Apple for sale in the United States. Although Foxconn does final assembly, it doesn't make any of the components and, in fact, charges Apple only about \$6 for assembling each iPad.

The following table lists just some of the suppliers of iPad components.

Firm	Location of the firm	The iPad component the firm supplies
AKM	Japan	Motion sensor
AU Optronics	Taiwan	Display
Avago Technologies	United States (Pennsylvania)	Wireless technology
Bosch Sensortec	Germany	Accelerometer
Broadcom	United States (California)	Touchscreen controller and wireless chip
Cirrus Logic	United States (Texas)	Audio chip
Corning	United States (New York)	Glass screen cover
Dialog Semiconductor	Germany	Power management chip
Elpida	United States (Idaho)	System memory
Infineon Technologies	Germany	Semiconductors
LG Electronics	South Korea	Display
Qualcomm	United Kingdom	Wireless section
Samsung	South Korea	Display, flash memory, and applications processor
Sharp	Japan	Display
SK Hynix	South Korea	Flash memory
Skyworks Solutions	United States (Massachusetts)	Wireless technology
STMicroelectronics	France/Italy	Motion sensors
Texas Instruments	United States (Texas)	Touchscreen controller
Toshiba	Japan	Flash memory
TriQuint Semiconductor	United States (Oregon)	Wireless technology

Each of these suppliers in turn relies on its own suppliers. For example, Broadcom designs the touchscreen controller for the iPad and supplies it to Apple, but it does not manufacture the components of the controller or assemble them. To manufacture the components, Broadcom relies on SilTerra, based in Malaysia; SMIC, based in mainland China; and Taiwan Semiconductor Manufacturing Corporation (TSMC) and UMC, based in Taiwan. TSMC's factories are for the most part not in Taiwan but in mainland China and Eastern Europe. To assemble the components, Broadcom uses several companies, including Amkor Technology, based in Chandler, Arizona, and STATS ChipPAC, based in Singapore.

All told, an iPad contains hundreds of parts that are designed, manufactured, and assembled by firms around the world. Many of these firms are not even aware of which other firms are also producing components for the iPad. Few of the managers of these firms have met managers of the other firms or shared knowledge of how their particular components are produced. In fact, no one person from Tim Cook, the chief executive officer of Apple, on down possesses the knowledge of how to produce all the components that are assembled into an iPad. Instead, the invisible hand of the market

has led these firms to contribute their knowledge and resources to the process that ultimately results in an iPad available for sale in a store in the United States. Apple has so efficiently organized the process of producing the iPad that you can order a custom iPad with a personal engraving and have it delivered from an assembly plant in China or Brazil to your doorstep in the United States in as little as three days.

The Role of the Entrepreneur in the Market System

Entrepreneurs are central to the working of the market system. An **entrepreneur** is someone who operates a business. Entrepreneurs first determine what goods and services they believe consumers want and then decide how to produce those goods and services most profitably, using the available factors of production—labor, capital, and natural resources. Successful entrepreneurs are able to search out opportunities to provide new goods and services. Frequently these opportunities are created by new technology. Consumers and existing businesses often do not at first realize that the new technology makes new products feasible. For example, even after the development of the internal combustion engine had made automobiles practicable, Henry Ford remarked, “If I had asked my customers what they wanted, they would have said a faster horse.” Because consumers often cannot evaluate a new product before it exists, some of the most successful entrepreneurs, such as the late Steve Jobs of Apple, rarely use *focus groups*, or meetings with consumers in which the consumers are asked what new products they would like to see. Instead, entrepreneurs think of products that consumers may not even realize they need, such as, in Jobs’s case, an MP3 player—the iPod—or a tablet computer—the iPad. Entrepreneurs are important to the economy because they are often responsible for making new products widely available to consumers, as Henry Ford did with the automobile and Steve Jobs did with the iPod.

Entrepreneur Someone who operates a business, bringing together the factors of production—labor, capital, and natural resources—to produce goods and services.

The firms that entrepreneurs found are typically small at first, as Apple and Ford were. Table 2.3 lists some of the important products entrepreneurs at small firms introduced during the twentieth century.

Entrepreneurs put their own funds at risk when they start businesses. If they are wrong about what consumers want or about the best way to produce goods and services, they can lose those funds. In fact, it is not unusual for entrepreneurs who eventually achieve great success to fail at first. For instance, early in their careers, both Henry Ford and Sakichi Toyoda, who eventually founded the Toyota Motor Corporation, started companies that quickly failed. Research by Richard Freeman of Harvard University has shown that a typical entrepreneur earns less than an employee at a large firm who has the same education and other characteristics. Few entrepreneurs make the fortunes earned by Mark Zuckerberg (Facebook), Steve Jobs (Apple), or Bill Gates (Microsoft).

Entrepreneurs make a vital contribution to economic growth through their roles in responding to consumer demand and introducing new products. Government policies that encourage entrepreneurship are also likely to increase economic growth and raise the standard of living. In the next section, we consider the legal framework required for a successful market in which entrepreneurs can succeed.

The Legal Basis of a Successful Market System

In a free market, government does not restrict how firms produce and sell goods and services or how they employ factors of production. But the absence of government intervention is not enough for the market system to work well. Government has to take active steps to provide a *legal environment* that will allow markets to operate efficiently.

Note that historians sometimes dispute the identity of the person who first commercially developed a particular product.

Protection of Private Property For the market system to work well, individuals must be willing to take risks. Someone with \$250,000 can be cautious and keep it safely in a bank—or even in cash, if the person doesn’t trust banks. But the market system won’t work unless a significant number of people are willing to risk their funds by investing them in businesses. Investing in businesses is risky in any country. Many businesses fail every year in the United States and other high-income countries. But in high-income countries, someone who starts a new business or invests in an existing business doesn’t have to worry that the government, the military, or criminal gangs might decide to seize the business or demand payments for not destroying it. Unfortunately, in many poor countries, business owners are not well protected from having their businesses seized by the government or from having their profits taken by criminals. Where these problems exist, opening a business can be extremely risky. Cash can be concealed easily, but a business is difficult to conceal or move.

Property rights The rights individuals or firms have to the exclusive use of their property, including the right to buy or sell it.

Property rights are the rights individuals or firms have to the exclusive use of their property, including the right to buy or sell it. Property can be physical property, such as a store or factory. Property can also be intangible, such as the right to an idea. Two amendments to the U.S. Constitution guarantee property rights: The Fifth Amendment states that the federal government shall not deprive any person “of life, liberty, or property, without due process of law.” The Fourteenth Amendment extends this guarantee to the actions of state governments: “No state . . . shall deprive any person of life, liberty, or property, without due process of law.” Similar guarantees exist in every high-income

country. Unfortunately, in many developing countries, such guarantees do not exist or are poorly enforced.

In any modern economy, *intellectual property rights* are very important. Intellectual property includes books, films, software, and ideas for new products or new ways of producing products. To protect intellectual property, the federal government grants a *patent* that gives an inventor—often a firm—the exclusive right to produce and sell a new product for a period of 20 years from the date the patent was filed. For instance, because Microsoft has a patent on the Windows operating system, other firms cannot sell their own versions of Windows. The government grants patents to encourage firms to spend money on the research and development necessary to create new products. If other companies could freely copy Windows, Microsoft would not have spent the funds necessary to develop it. Just as a new product or a new method of making a product receives patent protection, new books, films, and software receive *copyright* protection. Under U.S. law, the creator of a book, film, or piece of music has the exclusive right to use the creation during the creator's lifetime. The creator's heirs retain this exclusive right for 70 years after the death of the creator.

In providing copyright protection for only a limited time, Congress provides economic incentives to creators while eventually—after the period of copyright has ended—allowing the creators' works to be freely available to others. The longer the period of copyright, the longer the creator (or the creators' family) can restrict others from using the work.

Making the Connection

MyEconLab Video

An Elementary Case of Copyright

The U.S. Congress provides copyright protection to authors to give them an economic incentive to invest the time and effort required to write a book. While a book is under copyright, only the author—or whoever the author sells the copyright to—can

legally publish a paper or digital copy of the book. Once the copyright expires, however, the book enters the *public domain*, and anyone is free to publish the book. Copies of classic books written in the 1800s, such as Mark Twain's *Huckleberry Finn* and Charles Dickens's *Oliver Twist*, are available from many publishers that do not have to pay a fee to the authors' heirs.

Arthur Conan Doyle was a doctor in England when he published his first story featuring the detective Sherlock Holmes in 1887. Anyone who wants to publish any of the Sherlock Holmes stories that Doyle wrote from 1887 through the end of 1922 is free to do so. But the last 10 Sherlock Holmes stories that Doyle wrote from 1923 to 1927 remain under copyright protection. Doyle's heirs argue that because the author continued to develop the personalities of Sherlock Holmes and his companion Dr. John Watson in the 10 stories that remain under copyright protection, the characters cannot be used in new books, films, or television shows without payment. Doyle's heirs have asked anyone who wants to include Holmes in a new work to pay them a fee of \$5,000 per use.

The producers of two recent Sherlock Holmes films starring Robert Downey, Jr., and the producers of the television series *Sherlock*, starring Benedict Cumberbatch, and *Elementary*, starring Jonny Lee Miller, agreed to pay the fee, as have most authors of books using Holmes as a character. In 2011, when Leslie S. Klinger published *A Study in Sherlock*, a collection of new stories involving Sherlock Holmes, his publisher insisted that he pay the usual fee to Doyle's descendants. But two years later, when Klinger decided to publish another collection, *In the Company of Sherlock Holmes*, he decided that rather than pay the fee he would sue Doyle's descendants, hoping the federal courts would rule against their copyright claims.

Federal Appeals Judge Richard Posner—who is also an economist—eventually ruled in favor of Klinger. He argued that copyright law did not allow authors or their heirs to require fees for the use of characters from stories in the public domain. He also noted that, “the longer the copyright term is, the less public-domain material there will be and so the greater will be the cost of authorship, because authors will have to obtain

Who owns the classic character Sherlock Holmes?

licenses from copyright holders for more material.” As a result of this ruling, for the first time since 1887, anyone can use Sherlock Holmes as a character in a book, television show, or movie without having to pay a fee.

Your Turn: Test your understanding by doing related problems 3.15 and 3.16 on page 129 at the end of this chapter.

Enforcement of Contracts and Property Rights Business activity often involves someone agreeing to carry out some action in the future. For example, you may borrow \$20,000 to buy a car and promise the bank—by signing a loan contract—that you will pay back the money over the next five years. Or Facebook may sign a licensing agreement with a small technology company, agreeing to use that company’s technology for a period of several years in return for a fee. Usually these agreements take the form of legal contracts. For the market system to work, businesses and individuals have to rely on these contracts being carried out. If one party to a legal contract does not fulfill its obligations—perhaps the small company had promised Facebook exclusive use of its technology but then begins licensing it to other companies—the other party can go to court to have the agreement enforced. Similarly, if you believe that the federal or state government has violated your property rights under the Fifth or Fourteenth Amendments, you can go to court to have your rights enforced.

But going to court to enforce a contract or property rights will be successful only if the court system is independent and judges are able to make impartial decisions on the basis of the law. In the United States and other high-income countries, the court systems have enough independence from other parts of the government and enough protection from intimidation by outside forces—such as criminal gangs—that they are able to make their decisions based on the law. In many developing countries, the court systems lack this independence and will not provide a remedy if the government violates property rights, or if a person with powerful political connections decides to violate a business contract.

If property rights are not well enforced, fewer goods and services will be produced. This reduces economic efficiency, leaving the economy inside its production possibilities frontier.

Economics in Your Life

The Trade-offs When You Buy a Car

At the beginning of the chapter, we asked you to think about two questions: What is the relationship between safety and fuel efficiency for gasoline-powered cars? and, Under what circumstances would it be possible for automobile manufacturers to make cars that are both safer and more fuel efficient? To answer the first question, you have to recognize that there is a trade-off between safety and fuel efficiency. With the technology available at any particular time, an automobile manufacturer can increase fuel efficiency by making a car smaller and lighter. But driving a lighter car increases your chances of being injured if you have an accident. The trade-off between safety and fuel efficiency would look much like the relationship in Figure 2.1 on page 101. To get more of both safety and gas mileage, automobile makers would have to discover new technologies that allow them to make cars lighter and safer at the same time. Such new technologies would make points like *G* in Figure 2.1 attainable.

Conclusion

We have seen that by trading in markets, people are able to specialize and pursue their comparative advantage. Trading on the basis of comparative advantage makes all participants in trade better off. The key role of markets is to facilitate trade. In fact, the market system is a very effective means of coordinating the decisions of millions of consumers, workers, and firms. At the center of the market system is the consumer. To be successful, firms must respond to the desires of consumers. These desires are communicated to firms through prices. To explore how markets work, we must study the behavior of consumers and firms. We continue this exploration of markets in Chapter 3, when we develop the model of demand and supply.

Before moving on to Chapter 3, read *An Inside Look* on the next page for a discussion of Apple's plans to produce an electric car.

BLOOMBERG

Apple Wants to Start Producing Cars as Soon as 2020

a Apple Inc., which has been working secretly on a car, is pushing its team to begin production of an electric vehicle as early as 2020, people with knowledge of the matter said.

The timeframe—automakers typically spend five to seven years developing a car—underscores the project's aggressive goals and could set the stage for a battle for customers with Tesla Motors Inc. and General Motors Co. Both automakers are targeting a 2017 release of an electric vehicle that can go more than 200 miles on a single charge and cost less than \$40,000. . . .

Apple, which posted record profit of \$18 billion during the past quarter, has \$178 billion in cash with few avenues to spend it. The Cupertino, California-based company's research and development costs were \$6.04 billion in the past year, and Chief Executive Officer Tim Cook is facing increased pressure to return cash to shareholders. . . .

Car Team

Tesla's success in creating a startup car company has shown that the traditional barriers of entry into the auto industry aren't as difficult to overcome as originally thought, said one person, who asked not to be identified because the matter is private. At the same time, automakers have struggled to bring technical leaps to car development, something that Silicon Valley is also seeking to

accomplish. For example, Google Inc. has invested in developing an autonomous vehicle since 2010.

b "Apple would have some advantages as a new entrant to the auto industry," including its cash, ability to connect with its own devices and the infancy of the electric-vehicle market, Barclays analysts Ben Reitzes and Brian Johnson wrote in a note to investors. "Finally, Apple's brand—arguably the most important advantage—is a big attraction for the next generation of car customers."

Apple may decide to scrap its car effort or delay it if executives are unhappy with progress, as they've done before with other secret projects, the people said. The car team, which already has about 200 people, began ramping up hiring within the past couple of months as the company sought out experts in technologies for batteries and robotics, said one of the people.

Battery Lawsuit

An experienced automaker typically spends five to seven years developing a new vehicle before bringing it to market, according to Dennis Virag, president of Automotive Consulting Group.

"If you're starting from scratch, you're probably talking more like 10 years," Virag said. "A car is a very complex technological machine."

A lawsuit filed this month gives a window into Apple's efforts to create an automotive team for the project. Apple began around June an "aggressive campaign to poach" employees from A123 Systems LLC, the Waltham, Massachusetts-based battery maker said in the lawsuit.

Apple hired five people from A123 and has tried to hire battery experts from LG Chem Ltd., Samsung Electronics Co., Panasonic Corp., Toshiba Corp. and Johnson Controls Inc., according to the lawsuit. . . .

Tesla CEO Elon Musk told Bloomberg Businessweek this month that Apple was seeking to hire away his workers, offering \$250,000 signing bonuses and 60 percent salary increases.

Bricks and Mortar

c "Apple is good at developing technology but car making is, and will continue to be, a bricks-and-mortar proposition," Matt DeLorenzo, an analyst at Kelley Blue Book, wrote in an e-mail. "Apple will need a partner, perhaps a Chinese manufacturer, with an infrastructure if it's going to hit the five-year goal."

Some parts of the automotive industry seem unfazed by Silicon Valley's increasing interest in the market. Last month, before Apple's efforts were revealed, Volkswagen AG Chief Executive Officer Martin Winterkorn brushed off the increasing competition.

"We're not afraid of these new competitors," Winterkorn said at a reception outside Stuttgart, Germany, according to a transcript obtained by Bloomberg. "The opposite is true: they encourage us to look more intensively into the chances of the digital world."

Key Points in the Article

Apple is on a growing list of companies exploring the electric vehicle market and has assembled a team of managers to develop and produce an electric vehicle as early as 2020. To meet this aggressive five-year timeframe, Apple has been aggressive in hiring away experts from a number of companies, including Samsung, Panasonic, Toshiba, battery maker A123 Systems, and electric car manufacturer Tesla. By taking advantage of its available cash, communications technology, and extensive and loyal customer base, Apple has developed the potential to produce a successful product that can effectively compete with electric vehicles manufactured by companies like Tesla and General Motors.

Analyzing the News

a With \$178 billion in cash, Apple tops the list of the world's most cash-rich companies. Apple has a history of developing innovative technology for its computers and smartphones, and it has the resources to continue developing these technological innovations while branching out into new markets. Apple also wants to keep the investors who bought its stock happy because they are the legal owners of the company. So Apple has to carefully choose new projects that help it remain successful and profitable. Once Apple decides which products to make, its managers must choose the quantities of these products to

make. The managers face trade-offs when choosing which products to make and how to make them.

Suppose that Apple does begin selling electric cars in 2020; that it produces two models, a two-door convertible and a four-door sedan; and that it has the capability of producing a total of 100,000 vehicles per month. This capacity is represented by PPF_{2020} in the figure below. This curve shows that Apple would have to sacrifice production (and therefore sales) of one type of vehicle to produce more of the other. If these vehicles are successful and the market grows, Apple will need to produce a larger number of these electric automobiles, which is represented by PPF_{2025} in the figure.

b Not only do companies have decisions to make when choosing which projects to pursue, but once a decision is made, a company may choose to delay or even kill a project if it proves difficult to develop or if the market for the product changes. Apple has a brand and an image to protect, and moving forward with projects that may not be successful, even after the company has invested substantial funds in developing them, could harm its reputation. Not mentioned in the article is that Apple has had its share of failed products, from computers like the \$10,000 Lisa in 1983 and the 16-pound Macintosh Portable in 1989 to the Pippin game console in 1995, which retailed for two to three times the price of the PlayStation and Nintendo consoles. In

some instances, a failed product can do more damage to a company than scrapping the development of the product even after millions of dollars have been invested.

c Automobile manufacturing is not part of Apple's core consumer electronics business, so the company needs a completely different set of manufacturing, service, and distribution skills. With such a tight timeline to bring its car to market, Apple will face a trade-off when deciding on the production of its electric vehicle. As Kelly Blue Book's Matt DeLorenzo stated, "Apple will need a partner, perhaps a Chinese manufacturer, with an infrastructure if it's going to hit the five-year goal." Should Apple decide to work with an outside firm in the production of its automobile rather than attempt to build the vehicle completely in-house, it will give up some level of control in exchange for a greater chance at producing a successful product in a short period of time.

Thinking Critically

1. Suppose that from 2020 to 2025, the resources Apple uses to produce its automobiles remain constant, while improvements in technology in 2025 allow Apple to produce the additional quantity of two-door convertibles shown in the figure below, but no additional four-door sedans. Draw a graph that illustrates this technology change. Be sure to show both the 2020 and the new 2025 $PPFs$. What is the opportunity cost to Apple of producing one four-door sedan in 2020? Briefly explain whether the opportunity cost will be the same in 2025.
2. Assume that the figure below accurately represents Apple's $PPFs$ for 2020 and 2025 and that in 2025 it has customer orders for 110,000 four-door sedans and 65,000 two-door convertibles. Explain whether Apple can fill all of these orders.

These $PPFs$ show the trade-off Apple's managers face between producing different types of cars, and how that trade-off may change over time.

LEARNING OBJECTIVE: Use a production possibilities frontier to analyze opportunity costs and trade-offs.

Summary

The **production possibilities frontier (PPF)** is a curve that shows the maximum attainable combinations of two goods that can be produced with available resources. The PPF is used to illustrate the trade-offs that arise from **scarcity**. Points on the PPF are technically efficient. Points inside the PPF are inefficient, and points outside the PPF are unattainable. The **opportunity cost** of any activity is the highest-valued alternative that must be given up to engage in that activity. Because of increasing marginal opportunity costs, production possibilities frontiers are usually bowed out rather than straight lines. This illustrates the important economic concept that the more resources that are already devoted to any activity, the smaller the payoff from devoting additional resources to that activity is likely to be. **Economic growth** is illustrated by an outward shift in the production possibilities frontier.

	Economics	Chemistry	Economics	Chemistry
A	5	0	95	70
B	4	1	93	78
C	3	2	90	84
D	2	3	86	88
E	1	4	81	90
F	0	5	75	91

The Prime Minister's economic advisor has to prepare a report that discusses the relevant factors to be considered. Using the concepts of opportunity cost and trade-offs, create a report with the necessary factors and discuss some of the main issues that need to be dealt with.

- 1.12 After obtaining approval for a new drug from the European Medicines Agency (EMA), the producers of the drug then need to negotiate its inclusion in prescription lists with the National Health Service (NHS) for every member state of the European Union (EU). In the United Kingdom, the National Institute for Health and Care Excellence (NICE) negotiates prices and allows for a drug's inclusion in prescription lists in public hospitals. Once included, the NHS has to pay the pharmaceutical company for the drug prescribed by NHS providers. Recent research argues that the prices agreed by NICE may be too high, effectively diverting funds away from other NHS programs. What trade-offs does the NHS face when new prescription drugs are introduced with much higher prices than existing drugs? Do you agree with the system requiring the NHS to cover every drug that has NICE approval? Briefly explain.

- 1.13 In the United Kingdom, health care purchasing decisions are made locally by clinical commissioning groups (CCGs). They are groups of general practitioners (GPs) that work together to plan and design local health services. Some doctors in England have recently been offered thousands of pounds to reduce the number of patients being referred to specialist care in order to cut costs for the National Health Service (NHS).

Dr. Peter Melton, clinical chief officer for North East Lincolnshire CCG, said the scheme was not about avoiding sending people to a hospital. He explained that the purpose was not focusing on referral reduction; it was focusing on better clinical and quality standards for patients. Fearing the possibility that the payment mechanism may lead to patients questioning the motives of the GP referral, Dr. Chand Nagpaul, from the British Medical Association, said that such schemes were a "financial contaminant" to patient-doctor trust.

Would it be more ethical to provide specialist care without worrying about the cost or by taking the cost into account? Briefly explain.

- 1.14 In *The Wonderful Wizard of Oz* and his other books about the Land of Oz, L. Frank Baum observed that if people's wants were limited enough, most goods would not be scarce. According to Baum, this was the case in Oz:

There were no poor people in the Land of Oz, because there was no such thing as money. . . . Each person was given freely by his neighbors whatever he required for his use, which is as much as anyone may reasonably desire. Some tilled the lands and raised great crops of grain, which was divided equally among the whole population, so that

all had enough. There were many tailors and dressmakers and shoemakers and the like, who made things that any who desired them might wear. Likewise there were jewelers who made ornaments for the person, which pleased and beautified the people, and these ornaments also were free to those who asked for them. Each man and woman, no matter what he or she produced for the good of the community, was supplied by the neighbors with food and clothing and a house and furniture and ornaments and games. If by chance the supply ever ran short, more

was taken from the great storehouses of the Ruler, which were afterward filled up again when there was more of any article than people needed. . . .

You will know, by what I have told you here, that the Land of Oz was a remarkable country. I do not suppose such an arrangement would be practical with us.

Do you agree with Baum that the economic system in Oz wouldn't work in the contemporary United States? Briefly explain why or why not.

Comparative Advantage and Trade, pages 106–112

LEARNING OBJECTIVE: Describe comparative advantage and explain how it serves as the basis for trade.

Summary

Fundamentally, markets are about **trade**, which is the act of buying and selling. People trade on the basis of comparative advantage. An individual, a firm, or a country has a **comparative advantage** in producing a good or service if it can produce the good or service at the lowest opportunity cost. People are usually better off specializing in the activity for which they have a comparative advantage and trading for the other goods and services they need. It is important not to confuse comparative advantage with absolute advantage. An individual, a firm, or a country has an **absolute advantage** in producing a good or service if it can produce more of that good or service using the same amount of resources. It is possible to have an absolute advantage in producing a good or service without having a comparative advantage.

Review Questions

- 2.1 What is absolute advantage? What is comparative advantage? Is it possible for a country to have a comparative advantage in producing a good without also having an absolute advantage? Briefly explain.
- 2.2 David Ricardo was the first economist to suggest that two countries can benefit from trade even if one was less productive in all sectors of the economy. Explain the reasoning behind this suggestion using the concepts of absolute and comparative advantage.

Problems and Applications

- 2.3 Look again at the information in Figure 2.4 on page 107. Choose a rate of trading cherries for apples different from the rate used in the text (15 pounds of cherries for 10 pounds of apples) that will allow you and your neighbor to benefit from trading. Prepare a table like Table 2.1 on page 108 to illustrate your answer.
- 2.4 By putting in one hour of labor, Britain can produce either 10 kilograms of cheese or 10 kilograms of grain. With the same amount of labor, Ireland can produce either 6 kilograms of cheese or 2 kilograms of grain. Assuming 10 hours of labor are available in each country draw the production possibilities frontiers for Ireland and Britain.
 - a. Which country has an absolute advantage in producing cheese? Who has an absolute advantage in producing grain? Explain your reasoning.
 - b. Which country has a comparative advantage in producing cheese? Who has a comparative advantage in producing grain? Briefly explain.
 - c. Will trade between Britain and Ireland be beneficial for both countries? Why or why not?
- 2.5 (**Related to the Don't Let This Happen to You on page 109**) In the 1950s, the economist Bela Balassa compared 28 manufacturing industries in the United States and Britain. In every one of the 28 industries, Balassa found that the United States had an absolute advantage. In these circumstances, would there have been any gain to the United States from importing any of these products from Britain? Explain.
- 2.6 (**Related to Solved Problem 2.2 on page 110**) Suppose the United Kingdom and Norway both produce oil and fish oil, which are sold for the same prices in both countries. The following table shows the combinations of both

goods that each country can produce in a day, measured in thousands of barrels, using the same amounts of capital and labor:

United Kingdom		Norway	
Oil	Fish oil	Oil	Fish Oil
0	8	0	4
2	6	1	3
4	4	2	2
6	2	3	1
8	0	4	0

- a. Who has the comparative advantage in producing oil? Explain.
- b. Can these two countries gain from trading oil and fish oil? Explain.
- 2.7 (Related to Solved Problem 2.2 on page 110) Suppose that France and Germany both produce schnitzel and wine. The following table shows combinations of the goods that each country can produce in a day:

France		Germany	
Wine (bottles)	Schnitzel (pounds)	Wine (bottles)	Schnitzel (pounds)
0	8	0	15
1	6	1	12
2	4	2	9
3	2	3	6
4	0	4	3
		5	0

- a. Who has a comparative advantage in producing wine? Who has a comparative advantage in producing schnitzel?
- b. Suppose that France is currently producing 1 bottle of wine and 6 pounds of schnitzel, and Germany is currently producing 3 bottles of wine and 6 pounds of schnitzel. Demonstrate that France and Germany can both be better off if they specialize in producing only one good and then trade for the other.
- 2.8 Refer to the data provided in problem 2.4. Now suppose once Britain and Ireland start trading, the price of 1 kilogram of grain is equal to 2 kilograms of cheese. Can both countries consume beyond their production possibilities frontiers? How?
- 2.9 If Nicaragua can produce with the same amount of resources twice as much coffee as Colombia, explain how Colombia could have a comparative advantage in producing coffee.
- 2.10 Imagine that the next time Real Madrid play Barcelona at the Bernabéu Stadium in Madrid, Real Madrid's star football player Cristiano Ronaldo has a temporary lapse in

judgment and plans to sell Real Madrid merchandise during the game as he realizes that he can sell five times more Real Madrid products than any other player. Likewise, imagine that you are a creative and effective manager at work and that you tell your employees that during the next six months, you plan to clean the offices because you can clean five times better than the cleaning staff. What error in judgment are both Cristiano Ronaldo and you making? Why shouldn't Ronaldo and you do what you are better than anyone else at doing?

- 2.11 After Russia seized what had formerly been the Ukrainian territory of Crimea in February 2014, the United States and many other countries imposed economic sanctions that reduced the ability of Russia to engage in international trade. A columnist writing in the *New York Times* noted, "If sanctions push Russia onto a path of greater self-reliance, its manufacturing and service industries will surely grow faster. . . ." If the columnist is correct about the effect of the sanctions, are the sanctions likely to improve the economic well-being of the average Russian in the long run? Briefly explain.

- 2.12 In colonial America, the population was spread thinly over a large area, and transportation costs were very high because it was difficult to ship products by road for more than short distances. As a result, most of the free population lived on small farms, where they not only grew their own food but also usually made their own clothes and very rarely bought or sold anything for money. Explain why the incomes of these farmers were likely to rise as transportation costs fell. Use the concept of comparative advantage in your answer.
- 2.13 In the past, some governments have favored being self-sufficient and only import products that cannot be produced domestically. Do you believe that this is a sound economic policy? Explain.
- 2.14 (Related to the Making the Connection on page 111) In discussing dividing up household chores, Emily Oster, an economist at the University of Chicago, advises, "No, you shouldn't always unload the dishwasher because you're better at it." If you are better at unloading the dishwasher, why shouldn't you be the one to unload it?

Source: Emily Oster, "You're Dividing the Chores Wrong," *Slate*, November 21, 2012.

- 2.15 (Related to the Making the Connection on page 111) The chapter mentions that in 1965, married women with children did an average of 32 hours of housework per week, and men did an average of only 4 hours of housework. It has recently been observed that women now spend lesser time doing housework and the opposite holds true for men. Do you think that economics can provide an explanation for this or would sociology be more appropriate?

2.3 The Market System, pages 112–121

LEARNING OBJECTIVE: Explain the basics of how a market system works.

Summary

A **market** is a group of buyers and sellers of a good or service and the institution or arrangement by which they come together to trade. **Product markets** are markets for goods and services, such as computers and medical treatment. **Factor markets** are markets for the **factors of production**, such as labor, capital, natural resources, and entrepreneurial ability. A **circular-flow diagram** shows how participants in product markets and factor markets are linked. Adam Smith argued in his 1776 book *The Wealth of Nations* that in a **free market**, where the government does not control the production of goods and services, changes in prices lead firms to produce the goods and services most desired by consumers. If consumers demand more of a good, its price will rise. Firms respond to rising prices by increasing production. If consumers demand less of a good, its price will fall. Firms respond to falling prices by producing less of a good. An **entrepreneur** is someone who operates a business. In the market system, entrepreneurs are responsible for organizing the production of goods and services. The market system will work well only if there is protection for **property rights**, which are the rights of individuals and firms to use their property.

Review Questions

- 3.1 Like the circular-flow diagram, the *Tableau économique* by François Quesnay can be considered as the first model of a whole economy. Why is the circular-flow diagram considered a ground-breaking contribution?
- 3.2 What are the two main categories of participants in markets? Which participants are of greatest importance in determining what goods and services are produced?
- 3.3 Explain the difference between product markets and factor markets.
- 3.4 Explain why people like Larry Page, co-founder of Google, play a fundamental role in market economies.
- 3.5 Very few economists would favor centrally planned economies, and few would favor an economy completely governed by markets. Why is a certain level of government intervention needed, even in market economies?
- 3.6 What are property rights? What role do they play in the working of a market system? Why are independent courts important for a well-functioning economy?

Problems and Applications

- 3.7 Identify whether each of the following transactions will take place in the factor market or in the product market and whether households or firms are supplying the good or service or demanding the good or service.
 - a. George buys a Tesla Model S.
 - b. Tesla increases employment at its Fremont plant.

- c. George works 20 hours per week at McDonald's.
- d. George sells the land he owns to McDonald's so that it can build a new restaurant.

- 3.8 (Related to the **Making the Connection** on page 115) In the context of the comparative advantage framework discussed in this Chapter, how can you explain the fact that the components of an iPad are produced by different firms in various parts of the world? Why is this important for global organizations?
- 3.9 (Related to the **Making the Connection** on page 115) Fiat is the largest automobile maker in Italy. Headquartered in Turin, in 2014 the company merged with Chrysler, creating a new parent company called Fiat Chrysler Automobiles (FCA). Fiat is at the center of a complex network of suppliers of car parts, and in Turin an estimated 10,000 people work directly for Fiat's suppliers. Some of these suppliers are international players for various car parts. Brembo, for example, is one of the market leaders in the development and production of braking systems. Is it necessary for the managers of all the firms that supply parts to Fiat to know how their components are assembled into Fiat's cars? Is it necessary for the chief executive officer (CEO) of Fiat to know this information? Briefly explain.

- 3.10 Evaluate the following argument: "Adam Smith's analysis of the market system is based on a fundamental flaw: He assumes that people are motivated by self-interest. But this isn't true. I'm not selfish, and most people I know aren't selfish."
- 3.11 Writing in the *New York Times*, Michael Lewis argued that "a market economy is premised on a system of incentives designed to encourage an ignoble human trait: self-interest." Do you agree that self-interest is an "ignoble human trait"? What incentives does a market system provide to encourage self-interest?
- 3.12 A market is an economic system in which individual buyers and sellers own most of the resources, controlling their use through voluntary decisions made in the marketplace. In this type of economy, two forces—self-interest and competition—play an important role. According to Adam Smith, individuals usually act in a rational way, motivated by self-interest. With this in mind, do you think an organization donating to charitable causes is a result of being motivated by self-interest and financial rewards? Briefly explain.

3.14 According to an article on alderleyedge.com, some farmers in Cheshire, a county in the north of England, are causing a “stink” by using animal manure for fertilizer. Organic manure is an effective and cheaper alternative to chemical fertilizers. In England, the time-period for distributing the compost and the quantities of manure that farmers are allowed to use are strictly regulated by the Environmental Agency, making it essential for individuals to contact the Environment Agency to register an exemption or apply for an environmental permit for composting waste. Some of the local residents, however, have complained about the odours to the City Council. While the City Council has powers to investigate the sources of the odours, farmers who follow the Environment Agency guidelines are protected from any legal action and from providing compensation or cessation of manure spreading.

a. What price signal did the farmers follow in their decision to use organic manure rather than chemical fertilizer?

b. According to the Environment Agency guidelines, do the farmers or the other residents of Cheshire have property rights to the smell of the air around the farms?)

3.15 (Related to the Making the Connection on page 119) The British historian Thomas Macaulay once remarked that copyrights are “a tax on readers.” In what sense are copyrights a tax on readers? If copyrights are a tax on readers, why do governments enact them?

3.16 (Related to the Making the Connection on page 119) In the court case over whether anyone could use Conan Doyle’s character Sherlock Holmes without paying a fee, Judge Posner argued that the first Sherlock Holmes story was written in 1887, so allowing the author’s descendants to continue to claim a copyright to the character raised the possibility of “perpetual, or at least nearly perpetual, copyright.” The judge also noted that the U.S. Constitution had given Congress the authority to grant copyright for only a limited time. What would be the disadvantages to the economy of allowing an author and his or her descendants to have a copyright forever on a book or character? Would there be any advantages? Briefly explain.

How Smart Is Your Watch?

Fashions can change quickly. For many years, most people wore wristwatches. With the popularity of cellphones in the 2000s, many people stopped wearing wristwatches—which was bad news for the watch industry. Once a product falls out of fashion, its sales are unlikely to return to past levels. Will watches prove an exception?

Until recently attempts to have watches do more than tell the time have not been successful. For instance, during the 1980s Texas Instruments and several other firms added small calculators to watches, but sales were limited. In 2004, Microsoft introduced the SPOT watch, which enabled users to receive instant messages, weather reports, and news headlines. But few consumers purchased it so the company stopped production of the watch in 2008. By 2013, several firms had introduced “smartwatches” that enabled users to make phone calls, text, take photos or videos, monitor their heart rates, and calculate calories burned while exercising.

In 2015, Apple introduced the Apple Watch, which combined most of the capabilities of the smartwatches from competing firms with popular features from Apple’s iPhone and iPad, such as access to the iTunes music store and Siri, the voice-activated personal assistant. The Apple Watch was immediately popular, with more than 2.5 million being sold during the first five weeks. These sales were higher than initial sales of Apple’s previous products—the iPod, iPhone, or

iPad. More than 25 other firms entered the smartwatch market, hoping to participate in the rapid growth of a hot product.

But there are no guarantees in a market system. Would the Apple Watch and its competitors succeed in bringing the wristwatch back into style, or would they fail like the Texas Instruments calculator watch and the Microsoft SPOT watch? Smartwatches have relatively high prices, are somewhat complicated to use, and have small screens that make it difficult to display photos or maps. Ultimately, the success of the smartwatch is likely to depend on whether consumers like the applications, or “apps,” on these watches and are willing to wear wristwatches again.

The intense competition among firms selling smartwatches is a striking example of how the market responds to changes in technology and consumer tastes. Although competition is not always good news for firms trying to sell products, it is great news for consumers because it increases the available choice of products and lowers the prices consumers pay for those products.

AN INSIDE LOOK on **page 156** discusses how the Apple smartwatch is inspiring firms to develop other wearable devices.

Economics in Your Life

Will You Buy a Smartphone or a Smartwatch?

You use your smartphone mainly to text, read e-mail, and keep track of your appointments. Your smartphone is old, though, and you are thinking of buying a new one ... or should you buy a smartwatch? What factors are most important in your decision: the features of a smartwatch versus a smartphone, or the relative prices of these products? If you know that you are soon going to get a raise at your job, would you be more likely to buy a smartwatch? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 155** at the end of this chapter.

In Chapter 1, we explored how economists use models to predict human behavior. In Chapter 2, we used the production possibilities frontiers (PPF) model to analyze scarcity and trade-offs. In this chapter and the next, we explore the model of demand and supply, which is the most powerful tool in economics, and use the model to explain how prices are determined.

Economic models are simplified versions of reality that are based on assumptions. In some cases, the assumptions of a model may not describe exactly the economic situation we are analyzing. For example, the model of demand and supply assumes that we are analyzing a **perfectly competitive market**, which is a market where there are many buyers and sellers, all the products sold are identical, and there are no barriers to new firms entering the market. These assumptions are very restrictive and apply exactly to only a few markets, such as the markets for wheat and other agricultural products. Experience has shown, however, that the model of demand and supply can be very useful in analyzing markets where competition among sellers is intense, even if there are relatively few sellers and the products being sold are not identical. In fact, in recent studies, the model of demand and supply has been successful in analyzing markets with as few as four buyers and four sellers. As we will see in this chapter, this model is often successful in predicting changes in quantities and prices in many markets.

We begin studying the model of demand and supply by discussing consumers and the demand side of the market, and then we turn to firms and the supply side. Throughout this text, we will apply this model to understand business, the economy, and economic policy.

Perfectly competitive market A market that meets the conditions of having (1) many buyers and sellers, (2) all firms selling identical products, and (3) no barriers to new firms entering the market.

3.1 The Demand Side of the Market

LEARNING OBJECTIVE: List and describe the variables that influence demand.

We saw in Chapter 2 that in a market system, consumers ultimately determine which goods and services will be produced. The most successful businesses are the ones that respond best to consumer demand. But what determines consumer demand for a product? Certainly, many factors influence the willingness of consumers to buy a particular product. For example, consumers who are considering buying a smartwatch, such as an Apple Watch or a Samsung Gear S, will make their decisions based on, among other factors, the income they have available to spend and the effectiveness of the advertising campaigns of the companies that sell smartwatches. For most consumers, the primary factor in their buying decision is the price of the product. So, we focus on this factor first. As we discuss demand, keep in mind that we are considering not what a consumer *wants* to buy but what the consumer is both willing and *able* to buy.

Demand Schedules and Demand Curves

Tables that show the relationship between the price of a product and the quantity of the product demanded are called **demand schedules**. The table in Figure 3.1 shows the number of smartwatches consumers would be willing and able to buy over the course of a week at five different prices. The amount of a good or service that a consumer is willing and able to purchase at a given price is called the **quantity demanded**. The graph in Figure 3.1 plots the numbers from the table as a **demand curve**, which shows the relationship between the price of a product and the quantity of the product demanded. (Note that, for convenience, we made the demand curve in Figure 3.1 a straight line, or linear. There is no reason that all demand curves need to be straight lines.) The demand curve in Figure 3.1 shows the **market demand**, which is the demand by all the consumers of a given good or service. The market for a product, such as restaurant meals, that is sold locally would include all the consumers in a city or a relatively small area. The market for a product, such as smartwatches, that is sold internationally would include all the consumers in the world.

250	7

MyEconLab Animation

Figure 3.1

A Demand Schedule and Demand Curve

As the price changes, consumers change the quantity of smartwatches they are willing and able to buy. We can show this as a *demand schedule* in a table or as a *demand curve* on a graph. The table and graph both show that as the price of smartwatches falls, the quantity demanded increases. When the price of smartwatches is \$450, consumers buy 3 million smartwatches per week. When the price falls to \$400, consumers buy 4 million. Therefore, the demand curve for smartwatches is downward sloping.

The demand curve in Figure 3.1 slopes downward because consumers will buy more smartwatches as the price falls. When the price of smartwatches is \$450, consumers buy 3 million smartwatches per week. When the price falls to \$400, consumers buy 4 million. Buyers demand a larger quantity of a product as the price falls because the product becomes less expensive relative to other products and because they can afford to buy more at a lower price.

MyEconLab Concept Check

The Law of Demand

The inverse relationship between the price of a product and the quantity of the product demanded is called the **law of demand**: Holding everything else constant, when the price of a product falls, the quantity demanded of the product will increase, and when the price of a product rises, the quantity demanded of the product will decrease. The law of demand holds for any market demand curve. Economists have found only a very few exceptions to this law.

MyEconLab Concept Check

What Explains the Law of Demand?

It makes sense that consumers will buy more of a good when its price falls and less of a good when its price rises, but let's look more closely at why this result holds. When the price of a product falls, consumers buy a larger quantity because of two effects, the *substitution effect* and the *income effect*:

1. The **substitution effect** refers to the change in the quantity demanded of a good that results because a change in price makes the good more or less expensive *relative* to other goods that are *substitutes*. When the price of smartwatches falls, people will substitute buying smartwatches for other goods, such as regular wristwatches or smartphones, such as the iPhone.
2. The **income effect** of a price change refers to the change in the quantity demanded of a good that results because a change in the good's price increases or decreases consumers' purchasing power. *Purchasing power* is the quantity of goods a consumer can buy with a fixed amount of income. When the price of a good falls, the increased purchasing power of consumers' incomes will usually lead them to purchase a larger quantity of the good. When the price of a good rises, the decreased purchasing power of consumers' incomes will usually lead them to purchase a smaller quantity of the good.

Although we can analyze them separately, the substitution effect and the income effect occur simultaneously whenever a price changes. So, a fall in the price of smartwatches leads consumers to buy more smartwatches both because the smartwatches are now less expensive relative to substitute products and because the purchasing power of consumers' incomes has increased.

MyEconLab Concept Check

Law of demand A rule that states that, holding everything else constant, when the price of a product falls, the quantity demanded of the product will increase, and when the price of a product rises, the quantity demanded of the product will decrease.

Substitution effect The change in the quantity demanded of a good that results from a change in price, making the good more or less expensive relative to other goods that are substitutes.

Income effect The change in the quantity demanded of a good that results from the effect of a change in the good's price on consumers' purchasing power.

Ceteris paribus (“all else equal”) condition The requirement that when analyzing the relationship between two variables—such as price and quantity demanded—other variables must be held constant.

Normal good A good for which the demand increases as income rises and decreases as income falls.

Holding Everything Else Constant: The *Ceteris Paribus* Condition

Notice that the definition of the law of demand contains the phrase *holding everything else constant*. In constructing the market demand curve for smartwatches, we focused only on the effect that changes in the price of smartwatches would have on the quantity consumers would be willing and able to buy. We were holding constant other variables that might affect the willingness of consumers to buy smartwatches. Economists refer to the necessity of holding all variables other than price constant in constructing a demand curve as the **ceteris paribus condition**. *Ceteris paribus* means “all else equal” in Latin.

What would happen if we allowed a change in a variable—other than price—that might affect the willingness of consumers to buy smartwatches? Consumers would then change the quantity they demanded at each price. We can illustrate this effect by shifting the market demand curve. A shift of a demand curve is *an increase or a decrease in demand*. A movement along a demand curve is *an increase or a decrease in the quantity demanded*. As Figure 3.2 shows, we shift the demand curve to the right if consumers decide to buy more smartwatches at each price, and we shift the demand curve to the left if consumers decide to buy less at each price.

Variables That Shift Market Demand

Many variables other than price can influence market demand. These five are the most important:

- Income
- Prices of related goods
- Tastes
- Population and demographics
- Expected future prices

We next discuss how changes in each of these variables affect the market demand curve.

Income The income that consumers have available to spend affects their willingness and ability to buy a good. Suppose that the market demand curve in Figure 3.1 on page 133 represents the willingness of consumers to buy smartwatches when average household income is \$50,000. If average household income rises to \$52,000, the demand for smartwatches will increase, which we show by shifting the demand curve to the right. A good is a **normal good** when the demand for the good increases following a rise in income and decreases following a fall in income. Most goods are

MyEconLab Animation

Figure 3.2

Shifting the Demand Curve

When consumers increase the quantity of a product they want to buy at a given price, the demand curve shifts to the right, from D_1 to D_2 . When consumers decrease the quantity of a product they want to buy at a given price, the demand curve shifts to the left, from D_1 to D_3 .

normal goods, but some goods are *inferior goods*. A good is an **inferior good** when the demand for it decreases following a rise in income and increases following a fall in income. For instance, as your income rises, you might buy fewer cans of tuna or packages of instant noodles, and buy more shrimp or whole grain pasta. So, for you, canned tuna and instant noodles would be examples of inferior goods—not because they are of low quality but because you buy less of them as your income increases.

Prices of Related Goods The prices of other goods can also affect consumers' demand for a product. Consumers who would use a smartwatch primarily for checking the time, making phone calls, and keeping track of their appointments could use a smartphone instead. Goods and services that can be used for the same purpose are called **substitutes**. When two goods are substitutes, the more you buy of one, the less you will buy of the other. A decrease in the price of a substitute causes the demand curve for a good to shift to the left. An increase in the price of a substitute causes the demand curve for a good to shift to the right.

Suppose that the market demand curve in Figure 3.1 on page 133 represents the willingness and ability of consumers to buy smartwatches during a week when the average price of smartphones is \$400. If the average price of smartphones falls to \$300, consumers will demand fewer smartwatches at every price. We show this change by shifting the demand curve for smartwatches to the left.

Are Smartwatches Substitutes for Smartphones?

Two products are rarely perfect substitutes because consumers may find them more or less useful for some purposes. As Apple and other firms began selling smartwatches, a key question they needed to answer was whether consumers considered smartwatches close substitutes for smartphones. You can use either a smartwatch or a smartphone to check the time, send a text, keep a list of appointments, or use a GPS map. But you need a smartphone if you want to surf the Web or watch a movie, while you are better off buying a smartwatch if you want to monitor your heartbeat or keep track of how many calories you are burning while exercising.

So smartwatches and smartphones are substitutes—but they aren't *perfect* substitutes. To correctly forecast sales and produce the correct quantity of smartwatches, firms that sell them need to evaluate how close substitutes consumers consider smartwatches and smartphones to be. Many people who might consider buying a smartwatch already own a smartphone. So the closer consumers consider the two products to be as substitutes, the less likely they are to buy a smartwatch in addition to a smartphone.

When Apple introduced the Apple Watch in 2015, sales were initially very strong, which would seem to indicate that many consumers believed that the unique features of the smartwatch made it worth buying, even if they owned a smartphone. Some analysts, though, wondered how large future sales would be after people who buy each new electronic device soon after it hits the market—early adopters—had made their purchases. One early reviewer of the Apple Watch noted that he was unsure “that I need this thing on my wrist every day.” Similarly, the *Economist* magazine offered the opinion, “Apple seems unlikely to turn its watch into the next big must-have gadget. ... People are unlikely to want to shell out ... \$350 ... for something with so few extra functions.”

Other industry observers were more optimistic about the size of the market for smartwatches. Writing in the *Wall Street Journal*, one analyst argued that smartwatches performed several functions faster or more conveniently than smartphones. He concluded, “Billions of consumers who own a smartphone are likely to consider purchasing a smartwatch.” Given these different evaluations, it wasn't surprising that forecasts of sales of the Apple Watch during its first year varied widely from 8 million to 41 million.

Is the smartwatch a hot new must-have gadget, even for people who already own a smartphone?

In the end, as with most new products, the success of smartwatches depends on whether consumers see them as filling a need that other products don't meet. In other words, the less close a substitute consumers believe smartwatches to be for smartphones, the more likely they are to buy a smartwatch.

Complements Goods and services that are used together.

Goods and services that are used together—such as hot dogs and hot dog buns—are called **complements**. When two goods are complements, the more consumers buy of one, the more they will buy of the other. A decrease in the price of a complement causes the demand curve for a good to shift to the right. An increase in the price of a complement causes the demand curve for a good to shift to the left.

People use applications, or "apps," on their smartwatches. So, smartwatches and apps are complements. Suppose the market demand curve in Figure 3.1 represents the willingness of consumers to buy smartwatches at a time when the average price of an app is \$1.99. If the average price of apps falls to \$0.99, consumers will buy more apps *and* more smartwatches, and the demand curve for smartwatches will shift to the right.

Tastes An advertising campaign for a product can influence consumer demand. If Apple, Samsung, LG, and other firms making smartwatches begin to advertise heavily, consumers are likely to buy more smartwatches at every price, and the demand curve will shift to the right. An economist would say that the advertising campaign has affected consumers' *taste* for smartwatches. Taste is a catchall category that refers to the many subjective elements that can enter into a consumer's decision to buy a product. A consumer's taste for a product can change for many reasons. Sometimes trends play a substantial role. For example, the popularity of low-carbohydrate diets caused a decline in demand for some goods, such as bread and donuts, and an increase in demand for fish. In general, when consumers' taste for a product increases, the demand curve will shift to the right, and when consumers' taste decreases, the demand curve will shift to the left.

Population and Demographics As the population of a country increases, the number of consumers and the demand for most products will increase. The **demographics** of a population refers to its characteristics, with respect to age, race, and gender. As the demographics of a country or region change, the demand for particular goods will increase or decrease because different categories of people tend to have different preferences for those goods. For instance, the U.S. Census Bureau forecasts that Hispanics will increase from 18 percent of the U.S. population in 2015 to 26 percent in 2050. This increase will expand demand for Spanish-language books, Web sites, and cable television channels, among other goods and services.

Demographics The characteristics of a population with respect to age, race, and gender.

McDonalds introduced new products to appeal to millennials as sales of Big Macs declined.

Making the Connection

MyEconLab Video

Tough Times for Big Macs and Golf

Changing demographics can affect the demand for products. Clearly, the usefulness of products may vary with age. For example, when birth rates are high, the demand for formula, diapers, and other baby products increases. Similarly, when there are more older people, the demand for nursing homes increases. Some retail analysts believe, though, that tastes for products may also differ across generations, so that some products may remain popular with older generations while declining in popularity with younger generations. There are no exact definitions of generations, but the chart on the next page shows common labels.

Years Born	Generation Label	Age Range in 2015	Number of People in the Generation in 2015
1946–1964	Baby boom generation	51–69	79 million
1965–1984	Generation X	31–50	83 million
1985–2004	Millennials, or Generation Y	11–30	87 million

The millennials outnumber the two generations that preceded them, but the size of each generation doesn't tell the whole story for retailers. Market research indicates that consumers between the ages of 18 and 49 account for a large fraction of all retail sales. This fact helps explain why firms are willing to pay high prices to run commercials on television programs, such as NBC's *The Voice*, that this "prime demographic" watches. Note that the whole of the baby boom generation is now older than this age group. Members of generation X are also beginning to age out of this group, and over time millennials will begin to make up the bulk of this demographic.

Because of their importance as consumers, firms become concerned if millennials don't have a strong demand for their products. Consider problems that McDonald's and Dick's Sporting Goods were facing in 2015. Millennials were shifting from buying Big Macs to visiting "fast casual" restaurants, such as Chipotle Mexican Grill and Panera Bread. In 2014, the revenue and profits of McDonald's both declined for the first time in more than 30 years. McDonald's was suffering particular problems with college-age consumers. The number of consumers aged 19 to 21 who visit McDonald's at least once per month declined 15 percent between 2011 and 2015.

Dick's Sporting Goods faced a similar problem with demand for golf clubs and other golf equipment. The average age of people who regularly play golf has increased over time and was 56 in 2015. During the past five years, the number of people aged 18 to 34 who played at least one round of golf during the year has been continually declining. As fewer young people play golf, sales of golf equipment, rounds of golf at golf courses, and ratings of golf tournaments on television have all declined. Sales of golf equipment at Dick's declined by more than 15 percent between 2013 and 2015.

How should a business respond if the demand for its products is decreasing among younger consumers? The answer depends partly on whether offering different products or changing existing products might increase demand from these consumers. McDonald's tried this strategy by introducing McWrap sandwiches—tortillas stuffed with chicken or vegetables—and other new meals to appeal to millennials. It also planned to use healthier ingredients by, for example, reducing the use of chicken that had been fed antibiotics while being raised. Dick's decided that it probably could not revive demand for its golf equipment. The chain laid off most of the golf pros who had been working in its stores, and reduced the number of golf clubs and golf balls and the amount of golf clothing it offered for sale.

As firms make plans for the long run, they have to take into account how changing demographics may affect demand for their products.

Expected Future Prices Consumers choose not only which products to buy but also when to buy them. For instance, if enough consumers become convinced that houses will be selling for lower prices in three months, the demand for houses will decrease now, as some consumers postpone their purchases to wait for the expected

price decrease. Alternatively, if enough consumers become convinced that the price of houses will be higher in three months, the demand for houses will increase now, as some consumers try to beat the expected price increase.

A Change in Demand versus a Change in Quantity Demanded

If the price of smartwatches falls from \$450 to \$400, the result will be a movement along the demand curve from point A to point B—an increase in quantity demanded from 3 million to 4 million. If consumers' incomes increase, or if another factor changes that makes consumers want more of the product at every price, the demand curve will shift to the right—an increase in demand. In this case, the increase in demand from D_1 to D_2 causes the quantity of smartwatches demanded at a price of \$450 to increase from 3 million at point A to 5 million at point C.

A Change in Demand versus a Change in Quantity Demanded

It is important to understand the difference between a *change in demand* and a *change in quantity demanded*. A change in demand refers to a shift of the demand curve. A shift occurs if there is a change in one of the variables—*other than the price of the product*—that affects the willingness of consumers to buy the product. A change in quantity demanded refers to a movement along the demand curve as a result of a change in the product's price. Figure 3.3 illustrates this important distinction. If the price of smartwatches falls from \$450 to \$400, the result will be a movement along the demand curve from point A to point B—an increase in quantity demanded from 3 million to 4 million. If consumers' incomes increase, or if another factor changes that makes consumers want more of the product at every price, the demand curve will shift to the right—an increase in demand. Forecasting the Demand for iPhones

One of the most important decisions that managers of any large firm face is choosing which new products to develop. A firm must devote people, time, and money to design a new product, negotiate with suppliers, create a marketing campaign, and perform many other tasks. But any firm has only limited resources and so faces a trade-off: Resources used to develop one product will not be available to develop another product. Ultimately, the products a firm chooses to develop will be those that it believes will be the most profitable. So, to decide which products to develop, firms need to forecast the demand for those products.

David Sobotta, who worked at Apple for 20 years and eventually became its national sales manager, has described discussions at Apple during 2002 about whether to develop a tablet computer. According to Sobotta, representatives of the U.S. National Institutes of Health urged Apple to develop a tablet computer, arguing that it would be particularly useful to doctors, nurses, and hospitals. In 2001, Bill Gates, chairman of Microsoft, had predicted that “within five years ... [tablet PCs] will be the most popular form of PC sold in America.” Apple's managers decided not to develop a tablet computer, however, because they believed the technology available at that time was too complex for an average computer user, and they also believed that the demand from doctors and nurses

Will demand for iPhones continue to grow despite increasing competition?

would be small. Apple's forecast was correct. Despite Bill Gates's prediction, in 2006, tablet computers made up only 1 percent of the computer market. According to Sobotta, "Apple executives had a theory that the route to success will not be through selling thousands of relatively expensive things, but millions of very inexpensive things like iPods."

Apple continued to work on smartphones, developing the technology to eliminate keyboards in favor of touchscreen displays. Rather than proceed immediately to building a tablet computer, Steve Jobs, then Apple's CEO, realized he could use this technology in a different way: "I thought 'My God we can build a phone out of this.'" From its introduction in 2007, the iPhone was an immediate success. By mid-2015, Apple had sold more than 600 million iPhones worldwide.

As Apple attempts to forecast demand for its iPhone, it needs to consider two factors: competition from other firms producing smartphones and competition from substitute goods, including tablets and smartwatches. By 2015, industry analysts were divided as to whether Apple would be able to maintain its share of the smartphone market in the face of increasing competition from other firms. The outlook for substitute goods was also mixed. Smartphones were an increasing share of the overall worldwide cellphone market, so there are relatively few consumers left to switch to smartphones from basic cellphones. The increasing availability of apps, including mobile payment apps like Apple Pay that can be used in place of credit cards, was increasing the usefulness of smartphones. But some consumers preferred to use tablets, with their larger screens, for checking e-mail and surfing the Web. With apps like FaceTime or Skype, a tablet can be used to make phone calls. Another unknown was the extent to which sales of smartwatches might eventually cut into smartphone sales.

As any firm does in forecasting demand, Apple faced a trade-off: If it was too cautious in expanding capacity or buying components for smartphones, other firms might seize a large share of the market. But, if Apple was too optimistic, it ran the risk of spending on capacity to produce more units than it could actually sell—an outcome that might turn potential profits into losses. Apple has spent billions of dollars buying large quantities of motion sensors, screens, and other components from suppliers. That will be money well spent ... if the forecast of demand turns out to be accurate. Time will tell whether the future demand for smartphones will be as large as Apple and other firms were forecasting.

3.2 The Supply Side of the Market

LEARNING OBJECTIVE: List and describe the variables that influence supply.

Just as many variables influence the willingness and ability of consumers to buy a particular good or service, many variables influence the willingness and ability of firms to supply a good or service. The most important of these variables is price. The amount of a good or service that a firm is willing and able to supply at a given price is the **quantity supplied**. Holding other variables constant, when the price of a good rises, producing the good is more profitable, and the quantity supplied will increase. When the price of a good falls, selling the good is less profitable, and the quantity supplied will decrease. In addition, as we saw in Chapter 2, devoting more and more resources to the production of a good results in increasing marginal costs. For example, if Apple, Samsung, LG, and other firms increase production of smartwatches during a given time period, they are likely to find that the cost of producing additional smartwatches increases as their suppliers run existing factories for longer hours and pay higher prices for components

Quantity supplied The amount of a good or service that a firm is willing and able to supply at a given price.

MyEconLab Animation

Figure 3.4

A Supply Schedule and Supply Curve

As the price changes, Apple, Samsung, LG, and other firms producing smartwatches change the quantity they are willing to supply. We can show this as a *supply schedule* in a table or as a *supply curve* on a graph. The supply schedule and supply curve both show that as the price of smartwatches rises, firms will increase the quantity they supply. At a price of \$400 per smartwatch, firms will supply 6 million smartwatches per week. At a price of \$450, firms will supply 7 million.

and higher wages for workers. With higher marginal costs, firms will supply a larger quantity only if the price is higher.

Supply Schedules and Supply Curves

A **supply schedule** is a table that shows the relationship between the price of a product and the quantity of the product supplied. The table in Figure 3.4 is a supply schedule showing the quantity of smartwatches that firms would be willing to supply per month at different prices. The graph in Figure 3.4 plots the numbers from the table as a **supply curve**, which shows the relationship between the price of a product and the quantity of the product supplied. The supply schedule and supply curve both show that as the price of smartwatches rises, firms will increase the quantity they supply. At a price of \$400 per smartwatch, firms will supply 6 million smartwatches per week. At a higher price of \$450, firms will supply 7 million. (Once again, we are assuming for convenience that the supply curve is a straight line, even though not all supply curves are actually straight lines.) MyEconLab Concept Check

Supply schedule A table that shows the relationship between the price of a product and the quantity of the product supplied.

Supply curve A curve that shows the relationship between the price of a product and the quantity of the product supplied.

The Law of Supply

The *market supply curve* in Figure 3.4 is upward sloping. We expect most supply curves to be upward sloping, according to the **law of supply**, which states that, holding everything else constant, increases in price cause increases in the quantity supplied, and decreases in price cause decreases in the quantity supplied. Notice that the definition of the law of supply—like the definition of the law of demand—contains the phrase *holding everything else constant*. If only the price of the product changes, there is a movement along the supply curve, which is *an increase or a decrease in the quantity supplied*. As Figure 3.5 shows, if any other variable that affects the willingness of firms to supply a good changes, the supply curve will shift, which is *an increase or a decrease in supply*. When firms increase the quantity of a product they want to sell at a given price, the supply curve shifts to the right. The shift from S_1 to S_3 represents *an increase in supply*. When firms decrease the quantity of a product they want to sell at a given price, the supply curve shifts to the left. The shift from S_1 to S_2 represents *a decrease in supply*. MyEconLab Concept Check

Law of supply A rule that states that, holding everything else constant, increases in price cause increases in the quantity supplied, and decreases in price cause decreases in the quantity supplied.

Variables That Shift Market Supply

The following are the five most important variables that shift market supply:

- Prices of inputs
- Technological change
- Prices of related goods in production
- Number of firms in the market
- Expected future prices

We next discuss how changes in each of these variables affect the market supply curve.

MyEconLab Animation

Figure 3.5

Shifting the Supply Curve

When firms increase the quantity of a product they want to sell at a given price, the supply curve shifts to the right. The shift from S_1 to S_3 represents an *increase in supply*. When firms decrease the quantity of a product they want to sell at a given price, the supply curve shifts to the left. The shift from S_1 to S_2 represents a *decrease in supply*.

Technological change A positive or negative change in the ability of a firm to produce a given level of output with a given quantity of inputs.

Prices of Inputs The factor most likely to cause the supply curve for a product to shift is a change in the price of an *input*. An input is anything used in the production of a good or service. For instance, if the price of a component of smartwatches, such as memory chips, rises, the cost of producing smartwatches will increase, and smartwatches will be less profitable at every price. The supply of smartwatches will decline, and the market supply curve for smartwatches will shift to the left. Similarly, if the price of an input declines, the supply of smartwatches will increase, and the market supply curve will shift to the right.

Technological Change A second factor that causes a change in supply is **technological change**, which is a positive or negative change in the ability of a firm to produce a given level of output with a given quantity of inputs. Positive technological change occurs whenever a firm is able to produce more output using the same amount of inputs. In other words, the *productivity* of the firm's workers or machines has increased. If a firm can produce more output with the same amount of inputs, its costs will be lower, and the good will be more profitable to produce at any given price. As a result, when positive technological change occurs, the firm will increase the quantity supplied at every price, and its supply curve will shift to the right.

Negative technological change is relatively rare, although it could result from an earthquake or another natural disaster or from a war that reduces the ability of firms to supply as much output with a given amount of inputs. Negative technological change will raise firms' costs, and firms will earn lower profits from producing the good. Therefore, negative technological change will cause the market supply curve to shift to the left.

Prices of Related Goods in Production Firms often choose which good or service they will produce. Alternative goods that a firm could produce are called *substitutes in production*. Many of the firms that produce smartwatches also produce other consumer electronics. For example, Apple produces the iPhone and the iPad, and Samsung produces the Galaxy S smartphone and Galaxy Tab. These products typically use similar components and are often assembled in the same factories. If the price of smartphones increases relative to the price of smartwatches, smartphones will become more profitable, and Apple, Samsung, and other firms making smartwatches will shift some of their productive capacity away from smartwatches and toward smartphones. The firms will offer fewer smartwatches for sale at every price, so the supply curve for smartwatches will shift to the left.

Goods that are produced together are called *complements in production*. For example, the same geological formations that contain oil usually also contain natural gas. If the price of oil rises, oil companies that begin pumping more oil from these formations will also produce more natural gas. As a result, an increase in the price of oil will cause the supply curve for natural gas—a complement in production—to shift to the right.

Number of Firms in the Market A change in the number of firms in the market will change supply. When new firms *enter* a market, the supply curve shifts to the right, and when existing firms leave, or *exit*, a market, the supply curve shifts to the left. In 2015, for instance, Apple entered the market for smartwatches, which shifted the market supply curve to the right.

Expected Future Prices If a firm expects that the price of its product will be higher in the future, it has an incentive to decrease supply now and increase it in the future. For instance, if Apple believes that prices for smartwatches are temporarily low—perhaps because of a recession—it may store some of its production today to sell later on, when it expects prices to be higher.

Table 3.2 summarizes the most important variables that cause market supply curves to shift. Note that the table shows the shift in the supply curve that results from an *increase* in each of the variables. A *decrease* in these variables would cause the supply curve to shift in the opposite direction.

Figure 3.6

A Change in Supply versus a Change in Quantity Supplied

If the price of smartwatches rises from \$400 to \$450, the result will be a movement up the supply curve from point A to point B—an increase in the quantity supplied by Apple, Samsung, Nokia, and other firms from 6 million to 7 million. If the price of an input decreases, or if another factor changes that causes sellers to supply more of the product at every price, the supply curve will shift to the right—an increase in supply. In this case, the increase in supply from S_1 to S_2 causes the quantity of smartwatches supplied at a price of \$450 to increase from 7 million at point B to 9 million at point C.

**A Change in Supply versus a Change in Quantity Supplied**

We noted earlier the important difference between a change in demand and a change in quantity demanded. There is a similar difference between a *change in supply* and a *change in quantity supplied*. A change in supply refers to a shift of the supply curve. The supply curve will shift when there is a change in one of the variables—*other than the price of the product*—that affects the willingness of suppliers to sell the product. A change in quantity supplied refers to a movement along the supply curve as a result of a change in the product's price. Figure 3.6 illustrates this important distinction. If the price of smartwatches rises from \$400 to \$450, the result will be a movement up the supply curve from point A to point B—an increase in quantity supplied from 6 million to 7 million. 3.3 Market Equilibrium: Putting Demand and Supply Together

LEARNING OBJECTIVE: Use a graph to illustrate market equilibrium.

The purpose of markets is to bring buyers and sellers together. As we saw in Chapter 2, instead of being chaotic and disorderly, the interaction of buyers and sellers in markets ultimately results in firms being led to produce the goods and services that consumers want most. To understand this process, we first need to see how markets work to reconcile the plans of buyers and sellers.

In Figure 3.7, we bring together the market demand curve and the market supply curve for smartwatches. Notice that the demand curve crosses the supply curve at only one point. This point represents a price of \$350 and a quantity of 5 million smartwatches per week. Only at this point of **market equilibrium** is the quantity of smartwatches consumers are willing and able to buy equal to the quantity of smartwatches firms are willing and able to sell. In this case, the *equilibrium price* is \$350, and the *equilibrium quantity* is 5 million. As we noted at the beginning of the chapter, markets that have many buyers and sellers are competitive markets, and equilibrium in these markets is a **competitive market equilibrium**. In the market for smartwatches, there are many buyers but only about 25 firms. Whether 25 firms are enough for our model of demand and supply to apply to this market is a matter of judgment. In this chapter, we are assuming that the market for smartwatches has enough sellers to be competitive.

Market equilibrium A situation in which quantity demanded equals quantity supplied.

Competitive market equilibrium A market equilibrium with many buyers and sellers.

MyEconLab Animation

Figure 3.7

Market Equilibrium

Where the demand curve crosses the supply curve determines market equilibrium. In this case, the demand curve for smartwatches crosses the supply curve at a price of \$350 and a quantity of 5 million smartwatches. Only at this point is the quantity of smartwatches consumers are willing to buy equal to the quantity that Apple, Samsung, LG, and other firms are willing to sell: The quantity demanded is equal to the quantity supplied.

How Markets Eliminate Surpluses and Shortages

A market that is not in equilibrium moves toward equilibrium. Once a market is in equilibrium, it remains in equilibrium. To see why, consider what happens if a market is not in equilibrium. Suppose that the price in the market for smartwatches was \$400 rather than the equilibrium price of \$350. As Figure 3.8 shows, at a price of \$400, the quantity of smartwatches supplied would be 6 million, and the quantity of smartwatches demanded would be 4 million. When the quantity supplied is greater than the quantity demanded, there is a **surplus** in the market. In this case, the surplus is

Surplus A situation in which the quantity supplied is greater than the quantity demanded.

MyEconLab Animation

Figure 3.8 The Effect of Surpluses and Shortages on the Market Price

When the market price is above equilibrium, there will be a *surplus*. A price of \$400 for smartwatches results in 6 million smartwatches being supplied but only 4 million being demanded, or a surplus of 2 million. As Apple, Nokia, LG, and other firms cut the price to dispose of the surplus, the price will fall to the equilibrium price of \$350. When the market

price is below equilibrium, there will be a *shortage*. A price of \$250 results in 7 million smartwatches being demanded but only 3 million being supplied, or a shortage of 4 million. As firms find that consumers who are unable to find smartwatches available for sale are willing to pay higher prices to get them, the price will rise to the equilibrium price of \$350.

equal to 2 million smartwatches (6 million – 4 million = 2 million). When there is a surplus, firms will have unsold goods piling up, which gives them an incentive to increase their sales by cutting the price. Cutting the price will simultaneously increase the quantity demanded and decrease the quantity supplied. This adjustment will reduce the surplus, but as long as the price is above \$350, there will be a surplus, and downward pressure on the price will continue. Only when the price falls to \$350 will the market be in equilibrium.

If, however, the price were \$250, the quantity demanded would be 7 million, and the quantity supplied would be 3 million, as shown in Figure 3.8. When the quantity demanded is greater than the quantity supplied, there is a **shortage** in the market. In this case, the shortage is equal to 4 million smartwatches (7 million – 3 million = 4 million). When a shortage occurs, some consumers will be unable to buy smartwatches at the current price. In this situation, firms will realize that they can raise the price without losing sales. A higher price will simultaneously increase the quantity supplied and decrease the quantity demanded. This adjustment will reduce the shortage, but as long as the price is below \$350, there will be a shortage, and upward pressure on the price will continue. Only when the price rises to \$350 will the market be in equilibrium.

At a competitive market equilibrium, all consumers willing to pay the market price will be able to buy as much of the product as they want, and all firms willing to accept the market price will be able to sell as much of the product as they want. As a result, there will be no reason for the price to change unless either the demand curve or the supply curve shifts.

Shortage A situation in which the quantity demanded is greater than the quantity supplied.

Demand and Supply Both Count

Keep in mind that the interaction of demand and supply determines the equilibrium price. Neither consumers nor firms can dictate what the equilibrium price will be. No firm can sell anything at any price unless it can find a willing buyer, and no consumer can buy anything at any price without finding a willing seller.

Demand and Supply Both Count: A Tale of Two Letters

Which letter is likely to be worth more: one written by Abraham Lincoln or one written by his assassin, John Wilkes Booth? Lincoln is one of the greatest presidents, and many people collect anything he wrote. The demand for letters written by Lincoln surely would seem to be much greater than the demand for letters written by Booth. Yet, when R.M. Smythe and Co. auctioned off on the same day

a letter written by Lincoln and a letter written by Booth, the Booth letter sold for \$31,050, and the Lincoln letter sold for only \$21,850. Use a demand and supply graph to explain how the Booth letter has a higher market price than the Lincoln letter, even though the demand for letters written by Lincoln is greater than the demand for letters written by Booth.

Solving the Problem

Step 1: **Review the chapter material.** This problem is about prices being determined at market equilibrium, so you may want to review the section “Market Equilibrium: Putting Demand and Supply Together,” which begins on page 144.

Step 2: **Draw demand curves that illustrate the greater demand for Lincoln’s letters.** Begin by drawing two demand curves. Label one “Demand for Lincoln’s letters” and the other “Demand for Booth’s letters.” Make sure that the Lincoln demand curve is much farther to the right than the Booth demand curve.

Step 3: Draw supply curves that illustrate the equilibrium price of Booth's letters being higher than the equilibrium price of Lincoln's letters. Based on the demand curves you have just drawn, think about how it might be possible for the market price of Lincoln's letters to be lower than the market price of Booth's letters. This outcome can occur only if the supply of Lincoln's letters is much greater than the supply of Booth's letters. Draw on your graph a supply curve for Lincoln's letters and a supply curve for Booth's letters that will result in an equilibrium price of Booth's letters of \$31,050 and an equilibrium price of Lincoln's letters of \$21,850. You have now solved the problem.

Extra Credit: The explanation for this puzzle is that both demand and supply count when determining market price. The demand for Lincoln's letters is much greater than the demand for Booth's letters, but the supply of Booth's letters is very small. Historians believe that only eight letters written by Booth exist today. (Note that the supply curves for letters written by Booth and by Lincoln are upward sloping, even though only a fixed number of each of these letters is available and, obviously, no more can be produced. The upward slope of the supply curves occurs because the higher the price, the larger the quantity of letters that will be offered for sale by people who currently own them.)

3.4 The Effect of Demand and Supply Shifts on Equilibrium

LEARNING OBJECTIVE: Use demand and supply graphs to predict changes in prices and quantities.

We have seen that the interaction of demand and supply in markets determines the quantity of a good that is produced and the price at which it is sold. We have also seen that several variables cause demand curves to shift and other variables cause supply curves to shift. As a result, demand and supply curves in most markets are constantly shifting, and the prices and quantities that represent equilibrium are constantly changing. In this section, we look at how shifts in demand and supply curves affect equilibrium price and quantity.

The Effect of Shifts in Supply on Equilibrium

When Apple entered the market for smartwatches, the market supply curve for smartwatches shifted to the right. Figure 3.9 shows the supply curve shifting from S_1 to S_2 . When the supply curve shifts to the right, there will be a surplus at the original equilibrium price, P_1 . The surplus is eliminated as the equilibrium price falls to P_2 and the equilibrium quantity rises from Q_1 to Q_2 . If an existing firm exits the market, the supply curve will shift to the left, causing the equilibrium price to rise and the equilibrium quantity to fall.

MyEconLab Concept Check

The Effect of Shifts in Demand on Equilibrium

Because smartwatches are a normal good, when incomes increase, the market demand curve shifts to the right. Figure 3.10 shows the effect of a demand curve shifting to the right, from D_1 to D_2 . This shift causes a shortage at the original equilibrium price, P_1 . To eliminate the shortage, the equilibrium price rises to P_2 , and the equilibrium quantity rises from Q_1 to Q_2 . In contrast, if the price of a substitute good, such as smartphones, were to fall, the demand for smartwatches would decrease, shifting the demand curve to the left. When the demand curve shifts to the left, both the equilibrium price and quantity will decrease.

MyEconLab Concept Check

The Effect of Shifts in Demand and Supply over Time

Whenever only demand or only supply shifts, we can easily predict the effect on equilibrium price and quantity. But, what happens if *both* curves shift? For instance, in many markets, the demand curve shifts to the right over time as population and income

MyEconLab Animation

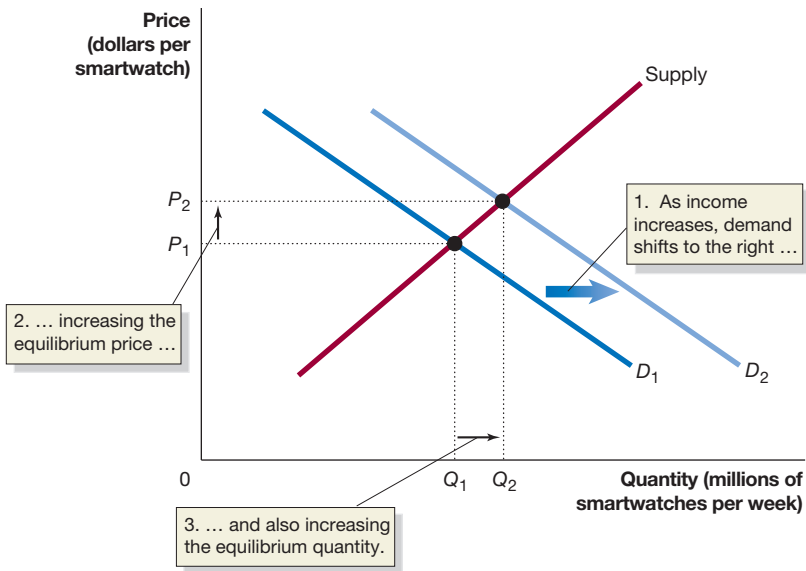

Figure 3.9

The Effect of an Increase in Supply on Equilibrium

If a firm enters a market, as Apple entered the market for smartwatches, the equilibrium price will fall, and the equilibrium quantity will rise:

1. As Apple enters the market for smartwatches, a larger quantity of smartwatches will be supplied at every price, so the market supply curve shifts to the right, from S_1 to S_2 , which causes a surplus of smartwatches at the original price, P_1 .
2. The equilibrium price falls from P_1 to P_2 .
3. The equilibrium quantity rises from Q_1 to Q_2 .

MyEconLab Animation

Figure 3.10

The Effect of an Increase in Demand on Equilibrium

Increases in income will cause the equilibrium price and quantity to rise:

1. Because smartwatches are a normal good, as income increases, the quantity demanded increases at every price, and the market demand curve shifts to the right, from D_1 to D_2 , which causes a shortage of smartwatches at the original price, P_1 .
2. The equilibrium price rises from P_1 to P_2 .
3. The equilibrium quantity rises from Q_1 to Q_2 .

increase. The supply curve also often shifts to the right as new firms enter the market and positive technological change occurs. Whether the equilibrium price in a market rises or falls over time depends on whether demand shifts to the right more than does supply. Panel (a) of Figure 3.11 shows that when demand shifts to the right more than supply, the equilibrium price rises, while panel (b) shows that when supply shifts to the right more than demand, the equilibrium price falls.

Table 3.3 on page 150 summarizes all possible combinations of shifts in demand and supply over time and the effects of the shifts on equilibrium price (P) and quantity (Q). For example, the entry in red in the table shows that if the demand curve shifts to the right and the supply curve also shifts to the right, the equilibrium quantity will

Figure 3.11 Shifts in Demand and Supply over Time

Whether the price of a product rises or falls over time depends on whether demand shifts to the right more than supply.

In panel (a), demand shifts to the right more than supply, and the equilibrium price rises:

1. Demand shifts to the right more than supply.
2. The equilibrium price rises from P_1 to P_2 .

In panel (b), supply shifts to the right more than demand, and the equilibrium price falls:

1. Supply shifts to the right more than demand.
2. The equilibrium price falls from P_1 to P_2 .

Table 3.3

How Shifts in Demand and Supply Affect Equilibrium Price (P) and Quantity (Q)

The entry in red shows that if the demand curve shifts to the right and the supply curve also shifts to the right, the equilibrium quantity will increase, while the equilibrium price may increase, decrease, or remain unchanged.

	Supply Curve Unchanged	Supply Curve Shifts to the Right	Supply Curve Shifts to the Left
Demand Curve Unchanged	Q unchanged P unchanged	Q increases P decreases	Q decreases P increases
Demand Curve Shifts to the Right	Q increases P increases	Q increases P increases, decreases, or is unchanged	Q increases, decreases, or is unchanged P increases
Demand Curve Shifts to the Left	Q decreases P decreases	Q increases, decreases, or is unchanged P decreases	Q decreases P increases, decreases, or is unchanged

increase, while the equilibrium price may increase, decrease, or remain unchanged. To make sure you understand each entry in the table, draw demand and supply graphs to check whether you can reproduce the predicted changes in equilibrium price and quantity. If the entry in the table says the predicted change in equilibrium price or quantity can be increase, decrease, or be unchanged, draw three graphs similar to panels (a) or (b) of Figure 3.11, one showing the equilibrium price or quantity increasing, one showing it decreasing, and one showing it unchanged.

Demand and Supply Trashes Plastic Recycling

Cities hire private firms to collect plastic bottles and containers for recycling. Until recently, recycling was profitable for these firms. The profits attracted thieves who would steal the used bottles and containers from recycling bins before the firms could pick them up. By 2015, though, firms no longer had to worry about thieves because they had bigger problems: Falling oil prices were decreasing the demand for recycled plastic at the same time that costs were rising as cities began requiring recycling firms to recycle many more types of plastic.

The development in the United States of hydraulic fracturing (“fracking”) has led to a sharp increase in the supply of oil and natural gas, resulting in a drop in their prices. Prices of products, including plastics, made from oil and natural gas have also fallen. Makers of plastic products such as bottles, food containers, and shopping bags, can use either newly produced plastic or recycled plastic. The figure below shows the market for recycled plastic. Because new plastic and recycled plastic are substitutes, as the price of newly produced plastic has fallen, the demand curve for recycled plastic has shifted to the left.

Many cities began plastic recycling by focusing on soda and milk bottles. But as recycling plans have become more ambitious, cities have required recycling firms to pick up nearly all plastics, including products like shopping bags and fast-food containers that are made of lower-quality plastic. It's costly for firms to separate different types of plastic before they can be processed and resold. This increase in cost shifts the supply curve for recycled plastic to the left. The figure shows that the equilibrium price of recycled plastic fell from P_1 to P_2 , and the equilibrium quantity fell from Q_1 to Q_2 . (Note that if the shift in the supply curve had been greater than the shift in the demand curve, the equilibrium price would have increased.)

As the quantity of recycled plastic declined, a number of recycling firms went out of business. Other firms stored plastic recyclables in the hopes that oil prices would eventually rise, increasing the demand for recyclable plastic.

The effects of these shifts in demand and supply were not good news for the recycling programs in many cities. Plastic recycling had been a steady source of revenue for local governments, but now they faced losing money by having to pay recycling companies to haul away some plastic the companies could no longer sell for a profit. Unless cities were willing to suffer losses or scale back their recycling programs, they would have to hope that higher oil prices might eventually increase the demand for recycled plastic.

Solved Problem 3.4

Can We Predict Changes in the Price and Quantity of Beef?

Whether you like to eat hamburger or roast beef, the source of the meat is a rancher who raises cattle. A news story discussed how years of drought had raised the cost to ranchers of raising cattle. At the same time, consumer tastes have been changing, leading to a decline in the demand for beef. Use demand and supply graphs to illustrate your answers to the following questions:

- Can we use this information to be certain whether the equilibrium quantity of beef will increase or decrease?
- Can we use this information to be certain whether the equilibrium price of beef will increase or decrease?

Solving the Problem

Step 1: Review the chapter material. This problem is about how shifts in demand and supply curves affect the equilibrium price, so you may want to review the section “The Effect of Shifts in Demand and Supply over Time,” which begins on page 148.

Step 2: Answer part (a) using demand and supply analysis. You are given the information that consumer tastes have changed, leading to a decline in demand for beef. So, the demand curve for beef has shifted to the left. You are also given the information that the cost of raising beef has increased. So, the supply curve for beef has also shifted to the left. The following graph shows both these shifts:

As Table 3.3 on page 150 summarizes, if the demand curve and the supply curve both shift to the left, the equilibrium quantity must decrease. Therefore, we can answer part (a) by stating that we are certain that the equilibrium quantity of beef will decrease.

Step 3: Answer part (b) using demand and supply analysis. The graph we drew in step 2 shows the equilibrium price of beef increasing. But given the information provided, the following graph would also be correct:

Unlike the graph in step 2, which shows the equilibrium price increasing, this graph shows the equilibrium price decreasing. The uncertainty about whether the equilibrium price will increase or decrease is consistent with what Table 3.3 shows happens when the demand curve and the supply curve both shift to the left. Therefore, the answer to part (b) is that we cannot be certain whether the equilibrium price of beef will increase or decrease.

Extra Credit: During 2013 and 2014, the equilibrium quantity of beef decreased while the equilibrium price of beef increased. We can conclude that *both* the decrease in demand for beef and the decrease in the supply of beef contributed to the decline in beef consumption. That the price of beef rose indicates that the decrease in supply had a larger effect on equilibrium in the beef market than did the decrease in demand.

Shifts in a Curve versus Movements along a Curve

When analyzing markets using demand and supply curves, remember that *when a shift in a demand or supply curve causes a change in equilibrium price, the change in price does not cause a further shift in demand or supply*. Suppose an increase in supply causes the price of a good to fall, while everything else that affects the willingness of consumers to buy the good is constant. The result will be an increase in the quantity demanded but not an increase in demand. For demand to increase, the whole curve must shift. The point is the same for supply: If the price of the good falls but everything else that affects the willingness of sellers to supply the good is constant, the quantity supplied decreases, but the supply does not. For supply to decrease, the whole curve must shift.

Don't Let This Happen to You

Remember: A Change in a Good's Price Does *Not* Cause the Demand or Supply Curve to Shift

Suppose a student is asked to draw a demand and supply graph to illustrate how an increase in the price of oranges would affect the market for apples, with other variables being constant. He draws the graph on the left and explains it as follows: "Because apples and oranges are substitutes, an increase in the price of oranges will cause an initial shift to the right in the demand curve for apples, from D_1 to D_2 . However, because this initial shift in the demand curve for apples results in a higher price for apples, P_2 , consumers will find apples less desirable, and the demand curve will shift to the left, from D_2 to D_3 , resulting in a final equilibrium price of P_3 ." Do you agree or disagree with the student's analysis?

MyEconLab Study Plan

You should disagree. The student has correctly understood that an increase in the price of oranges will cause the demand curve for apples to shift to the right. But, the second demand curve shift the student describes,

from D_2 to D_3 , will not take place. Changes in the price of a product do not result in shifts in the product's demand curve. Changes in the price of a product result only in movements along a demand curve.

The graph on the right shows the correct analysis. The increase in the price of oranges causes the demand curve for apples to increase from D_1 to D_2 . At the original price, P_1 , the increase in demand initially results in a shortage of apples equal to $Q_3 - Q_1$. But, as we have seen, a shortage causes the price to increase until the shortage is eliminated. In this case, the price will rise to P_2 , where both the quantity demanded and the quantity supplied are equal to Q_2 . Notice that the increase in price causes a decrease in the *quantity demanded*, from Q_3 to Q_2 , but does *not* cause a decrease in demand.

Economics in Your Life

Will You Buy a Smartphone or a Smartwatch?

At the beginning of this chapter, we asked you to consider how you might choose between buying a smartwatch and buying a smartphone. There are certain activities, such as watching YouTube or Netflix, that you can do on a smartphone but not on a smartwatch. There are other activities, such as tracking calories burned during a workout, that are probably easier to do on a smartwatch. If you can engage in the activities you like most on either device, then you probably consider the two devices to be close substitutes, and you are likely to buy the one with the lower price. Suppose that you are currently leaning toward buying a smartphone because its price is lower than the price of a comparable smartwatch. If an increase in your income would cause you to change your decision and buy the smartwatch, then the smartphone is an inferior good for you.

Conclusion

The interaction of demand and supply determines market equilibrium. The model of demand and supply is a powerful tool for predicting how changes in the actions of consumers and firms will cause changes in equilibrium prices and quantities. As we have seen in this chapter, we can use the model to analyze markets that do not meet all the requirements for being perfectly competitive. As long as there is intense competition among sellers, the model of demand and supply can often successfully predict changes in prices and quantities. We will use this model in the next chapter to analyze economic efficiency and the results of government-imposed price floors and price ceilings.

WALL STREET JOURNAL

Don't Underestimate Smartwatches: Wearable Devices Are Poised to Become Central to the Tech Ecosystem

a It's important to understand that like the iPhone before it, the Apple Watch isn't at all what its name would imply. Let's call it what it is: a wrist-top computer.

Just as smartphones have become supercomputers in our pockets, the Apple Watch and its many competitors, including Android-powered devices from Motorola and Samsung Electronics, are poised to become something more. And it is their central place in a larger ecosystem of apps and hardware, rather than any one thing that has been shown off recently, that will make them indispensable. ...

When a company like Google or Apple deliberately creates a place for other companies to sell their own, complementary wares, it is called a platform. Apple, more than Google, has mastered this art, having worked hard to give developers the tools to make apps for its mobile devices, plus a controlled environment in which to profit from them.

Fortunately, we don't have to wait for the Apple Watch and its app store to become available to get a glimpse of where things could be going. We have only to look at what pioneering companies in "wearables" are already working on, and then think about how their products will become a part of—or be absorbed

by—the Apple Watch and Android Wear ecosystems.

b "The vision of Sensoria is that the garment is the next ultra personal computer," says Sensoria CEO Davide Vigano. To illustrate his point, he rolls up his pants leg to show me a working prototype of the world's first smart sock.

I know, it sounds ridiculous. But, as he explains, with the help of an iPhone app that visualizes wireless signals sent by indiscernibly thin pressure sensors in the sock, it is good for runners who want to reduce their chance of injury. It is also potentially useful for monitoring the health of the elderly, since changes in gait are surprisingly predictive of other health issues. And yes, the smart sock is washable.

Sensoria also makes a smart bra and smart shirt, both of which can measure heart rate. And here's where things get really interesting: For all makers of wearables, which until recently have been dominated by the glorified pedometers known as fitness bands, fitness applications are just the beginning.

Using a few more of the same sensors it already carries, Sensoria's shirt could measure not just the frequency but the pattern of a wearer's heartbeat, Mr. Vigano tells me. Like the fingerprint sensor on new smartphones, the unique shape of the electrical signals generated by our hearts are a biometric. Add in a payment terminal not dissimilar from the ones that will roll out with Apple Pay, and the wearer of a Sensoria undergarment could soon find herself verifying payment for her next coffee via technology in her bra. ...

During Apple's presentation, Apple Vice President Kevin Lynch announced that BMW has developed an app for the Apple Watch that will allow users to lock and unlock their BMW i-series electric vehicles. And Mr. Martin told me that new blue-tooth-enabled locks from companies like Lockitron and Kwikset mean that the moment you walk up to a door while sporting a recognized wearable, it can unlock without a touch. ...

c Wearables won't just appeal to fitness nuts and quantified-self geeks. They will appeal to everyone, because they will be the primary, perhaps even the sole way we identify ourselves to a world full of smart objects.

Established makers of wearables have seen this trend and are already getting in front of it. On the same day that Apple announced its watch, Jawbone, maker of the UP wristband, said that it was opening up its quantified-self software so that anyone could connect it with devices other than the UP—including the Apple Watch.

Or in other words, amid the hype about the Apple Watch being a fitness device, or a timepiece, or a status symbol, it is the applications that Apple and others aren't even talking about, the ones that are thought up by countless developers jumping on board the platform, that will make us wonder how we ever got by without them. ...

Key Points in the Article

The introduction of the Apple Watch has inspired a number of companies to develop products that can utilize the smartwatch's technology. From the wearable technology of Sensoria's sensor-enhanced clothing to convenience items like Bluetooth-enabled door locks, these complementary products will allow consumers to use their smartwatches in new ways, including monitoring their health, making online purchases, and unlocking their front doors. In our technology-driven society, as more products and apps are developed for use with smartwatches, consumers could come to view these watches as a necessity rather than a luxury, which is what happened with smartphones.

Analyzing the News

a Smartwatches like the Apple Watch are a part of the relatively new product category of wearable technology. As with smartphones, a large part of the success of smartwatches will depend on the availability of desirable complementary products. One variable that shifts market demand for a product is the price of related goods. If the price of a complement decreases, market demand for the original product will increase, and if the price of a complement increases, market demand for the original product will decrease.

b Smart shirts are wearable technology garments that will sync with smartwatches,

so the two products are used together and are therefore complements. Suppose the figure below illustrates supply and demand for smart shirts. In 2015, the most basic smartwatch model had a price of about \$350, and at this price, the demand for smart shirts is represented by demand curve D_1 , with an equilibrium price of P_1 and an equilibrium quantity of Q_1 . If the price of smartwatches increases, this increase would, holding everything else constant, result in a decrease in demand for smart shirts. The demand curve would shift to the left, from D_1 to D_3 , resulting in a decrease in the equilibrium price from P_1 to P_3 and a decrease in the equilibrium quantity from Q_1 to Q_3 . If the price of smartwatches declines, the result will be an increase in demand for smart shirts. The demand curve would shift to the right, from D_1 to D_2 , resulting in an increase in the equilibrium price from P_1 to P_2 and an increase in the equilibrium quantity from Q_1 to Q_2 .

c As wearable technology grows in popularity, more firms will enter the market to compete with existing firms. Some of these firms will offer new products, while other firms will produce goods that compete with existing products. Suppose another apparel manufacturer designs a product to compete with smart shirts. This new product would be a substitute for smart shirts and, all else being equal, changes in the price of this new substitute would change the demand for smart shirts.

In the figure below, an increase in the price of a substitute would, holding everything else constant, increase the demand for smart shirts. The demand curve would shift to the right, from D_1 to D_2 , resulting in an increase in the equilibrium price from P_1 to P_2 and an increase in the equilibrium quantity from Q_1 to Q_2 . A decrease in the price of a substitute would have the opposite effect, resulting in a decrease in demand for smart shirts. The demand curve would shift to the left, from D_1 to D_3 , resulting in a decrease in the equilibrium price from P_1 to P_3 and a decrease in the equilibrium quantity from Q_1 to Q_3 .

Thinking Critically

1. Suppose a technological change allows firms to lower the cost of producing smart shirts. Explain if this change will affect the demand curve for smart shirts. How would this change affect the market for smartwatches?
2. In 2015, smartwatch producers had difficulty filling the orders they received. Draw a demand and supply graph to illustrate this situation. All else equal, what would you expect to happen in this market if this situation persisted into the future, and how would this affect the market for complementary products like smart shirts?

An increase in demand for smart shirts shifts the demand curve to the right. All else equal, equilibrium price and equilibrium quantity both increase. A decrease in demand has the opposite effect.

LEARNING OBJECTIVE: List and describe the variables that influence demand.

Summary

The model of demand and supply is the most powerful tool in economics. The model applies exactly only to **perfectly competitive markets**, where there are many buyers and sellers, all the products sold are identical, and there are no barriers to new sellers entering the market. But the model can also be useful in analyzing markets that don't meet all these requirements. The **quantity demanded** is the amount of a good or service that a consumer is willing and able to purchase at a given price. A **demand schedule** is a table that shows the relationship between the price of a product and the quantity of the product demanded. A **demand curve** is a graph that shows the relationship between the price of a product and the quantity of the product demanded. **Market demand** is the demand by all consumers of a given good or service. The **law of demand** states that *ceteris paribus*—holding everything else constant—the quantity of a product demanded increases when the price falls and decreases when the price rises. Demand curves slope downward because of the **substitution effect**, which is the change in quantity demanded that results from a price change making one good more or less expensive relative to another good, and the **income effect**, which is the change in quantity demanded of a good that results from the effect of a change in the good's price on consumer purchasing power. Changes in income, the prices of related goods, tastes, population and demographics, and expected future prices all cause the demand curve to shift. **Substitutes** are goods that can be used for the same purpose. **Complements** are goods that are used together. A **normal good** is a good for which demand increases as income increases. An **inferior good** is a good for which demand decreases as income increases. **Demographics** refers to the characteristics of a population with respect to age, race, and gender. A change in demand refers to a shift of the demand curve. A change in quantity demanded refers to a movement along the demand curve as a result of a change in the product's price.

- 1.3 What is the difference between a change in demand and a change in quantity demanded?
- 1.4 What is the law of demand? Use the substitution effect and the income effect to explain why an increase in the price of a product causes a decrease in the quantity demanded.
- 1.5 Suppose the price of white plain flour goes up by 50 percent. *Ceteris paribus*, will this affect the demand of brown plain flour?

Problems and Applications

- 1.6 Are cappuccinos and croissants complementary goods? Briefly explain your reasons. For each of the following pairs of products, briefly explain the relationship between them.
 - a. Cappuccinos and black coffees
 - b. Cappuccinos and Swedish trucks
 - c. Cappuccinos and cocoa powder
 - d. Cappuccinos and orange juice
- 1.7 An article published online by *The Economist* argues that “the popularity of electric cars in the years to come will depend much more on improvements to their performance than on the oil price.” Does the statement imply that internal-combustion engine cars and electric cars are substitutes, complements, or neither? Briefly explain.

- 1.9 What is the difference between a movement along the demand curve and a shift of the curve? Explain the two terms. State whether any of the following events in an Italian bar will result in either of the above.
- The barista offers a discount on cappuccinos for an entire day.
 - The barista offers a discount on all hot beverages apart from cappuccinos for a day.
 - The price of croissants doubles.
 - Italy enters a period of recession, with falling incomes.
 - The price of Swedish trucks goes up by 15 percent.
- 1.10 Suppose that the following table shows the quantity demanded of UGG boots at five different prices in 2016 and 2017:

Price	Quantity Demanded (thousands of pairs of boots)	
	2016	2017
\$160	5,000	4,000
170	4,500	3,500
180	4,000	3,000
190	3,500	2,500
200	3,000	2,000

Name two different variables that if their values were to change would cause the quantity demanded of UGG boots to change from 2016 to 2017, as indicated in the table.

- 1.11 With reference to the situation described in question 1.9, can you think of two additional examples or variables that would cause the demand curve for cappuccinos to shift leftward, that is, shift from D_1 to D_2 as shown in the figure below?

- 1.12 (Related to the Making the Connection on page 135) Is it always possible to ascertain whether two goods are substitutes, complementary goods, or that they do not bear any relationship with each other? Briefly explain.

- 1.13 (Related to the Making the Connection on page 136) Since 1979, China has had a policy that allows couples to have only one child. This policy has caused a change in the demographics of China. 3.2 The Supply Side of the Market, pages 140–144

LEARNING OBJECTIVE: List and describe the variables that influence supply.

Summary

The **quantity supplied** is the amount of a good that a firm is willing and able to supply at a given price. A **supply schedule** is a table that shows the relationship between the price of a product and the quantity of the product supplied. A **supply curve** is a curve that shows the relationship between the price of a product and the quantity of the product supplied. When the price of a product rises, producing the product is more profitable, and a greater amount will be supplied. The **law of supply** states that, holding everything else constant, the quantity of a product supplied increases when the price rises and decreases when the price falls. Changes in the prices of inputs, technology, the prices of related goods in production, the number of firms in a market, and expected future prices all cause the supply curve to shift. **Technological change** is a positive or negative change in the ability of a firm to produce a given level of output with a given quantity of inputs. A change in supply refers to a shift of the supply curve. A change in quantity supplied refers to a movement along the supply curve as a result of a change in the product’s price.

Market Equilibrium: Putting Demand and Supply Together, pages 144–147

LEARNING OBJECTIVE: Use a graph to illustrate market equilibrium.

Summary

Market equilibrium occurs where the demand curve intersects the supply curve. A **competitive market equilibrium** has a market equilibrium with many buyers and sellers. Only at this point is the quantity demanded equal to the quantity supplied. Prices above equilibrium result in **surpluses**, with the quantity supplied being greater than the quantity demanded. Surpluses cause the market price to fall. Prices below equilibrium result in **shortages**, with the quantity demanded being greater than the quantity supplied. Shortages cause the market price to rise.

Review Questions

- 3.1 What do economists mean by *market equilibrium*?
 3.2 What do economists mean by *shortage*? By *surplus*?
 3.3 Explain how market equilibrium is reached starting from a point at which the price of a good is above the equilibrium price.

Problems and Applications

- 3.4 Given that a market will reach its equilibrium price following a firm’s considerations over surpluses and shortages, do you think it correct to state that supply of goods and services is more important than the demand for them in such a situation?
 3.5 (Related to Solved Problem 3.3 on page 146) In *The Wealth of Nations*, Adam Smith discussed what has come to be known as the “diamond and water paradox”:
 Nothing is more useful than water: but it will purchase scarce anything; scarce anything

can be had in exchange for it. A diamond, on the contrary, has scarce any value in use; but a very great quantity of other goods may frequently be had in exchange for it.

Graph the market for diamonds and the market for water. Show how it is possible for the price of water to be much lower than the price of diamonds, even though the demand for water is much greater than the demand for diamonds.

- 3.6 (Related to Solved Problem 3.3 on page 146) Peter Kay is arguably the United Kingdom’s most successful comedian. In 2012, he broke the world record when his tour, *Tour That Doesn’t Tour*, became the world’s highest selling stand-up comedy tour, selling 1,140,798 tickets in 113 arena dates between February 2010 and November 2011. Peter Kay has sold more than 10 million DVDs and has a U.K.-chart number one to his name. He has become the first comedian to sell 10 million DVDs in the United Kingdom. Jason Manford is another comedian from Northern England. Jason’s live shows are considerably limited compared to Peter’s. In spite of the limited supply, the price of one ticket to Jason’s show is around £30. Tickets for Peter’s tour have been sold at £150. Use one graph to show both the demand and supply for live shows by Jason Manford and the demand and supply for live shows by Peter Kay. Show how it is possible for the price of Peter Kay’s shows to be higher than the price of Jason Manford’s shows, even though the supply of Peter Kay’s shows is larger than the supply of Jason Manford’s shows.

3.7 (Related to Solved Problem 3.3 on page 146) Comic book fans eagerly compete to buy copies of *Amazing Fantasy* No. 15, which contains the first appearance of the superhero Spider-Man. At the same time the publisher printed copies of the comic for the U.S. market, with the price printed on the cover in cents, it printed copies for the U.K. market, with the price printed on the cover in British pence. About 10 times as many U.S. copies of *Amazing Fantasy* No. 15 have survived as U.K. copies. Yet in auctions that occurred at about the same time, a U.S. copy sold for \$29,000, while a U.K. copy in the same condition sold for only \$10,755. Use a demand and supply graph to explain how the U.S. version of the comic has a higher price than the U.K. version, even though the supply of the U.S. version is so much greater than the supply of the U.K. version.

The Effect of Demand and Supply Shifts on Equilibrium, pages 148–154

LEARNING OBJECTIVE: Use demand and supply graphs to predict changes in prices and quantities.

Summary

In most markets, demand and supply curves shift frequently, causing changes in equilibrium prices and quantities. Over time, if demand increases more than supply, equilibrium price will rise. If supply increases more than demand, equilibrium price will fall.

Review Questions

- 4.1** Illustrate the demand and supply curves for lemonades and show what happens to the equilibrium price and quantity in the market in the following situations.
- The price of fresh fruit juice increases.
 - The price of sugar decreases.
- 4.2** What happens to the equilibrium price and the quantity of a good if both the demand curve and the supply curve shift towards the right? Briefly explain what would happen if the shift of the supply curve is seen to be greater than that of the demand curve.

Problems and Applications

4.3 (Related to the Chapter Opener on page 131) Suppose the demand for smartwatches increases rapidly during 2016. At the same time, six more firms begin producing smartwatches. A student remarks that, because of these events, we can't know for certain whether the price of smartwatches will rise or fall. Briefly explain whether you agree. Be sure to include a demand and supply graph of the market for smartwatches to illustrate your answer.

4.4 An article in *The Guardian* titled “Dairy Farmers Warned: Milk Prices Have Further to Fall” states dairy farmers have recently experienced a decline in demand for cow milk that was created by a reduction in demand for milk by cheese makers. Use a demand and supply graph to analyze the effect a fall in the demand for cheese on the equilibrium price of milk.

4.5 According to an article in *The Guardian*, the demand for bricks is declining in the United Kingdom because “a planning logjam has contributed to weakened demand.” At the same time, the supply of bricks was contained because brick producers decided to stockpile bricks. The article notes that despite the decline in the demand, the price of bricks might increase. Use a demand and supply graph of the brick market to illustrate how the price of bricks might increase as a result of these events. Be sure that all curves on your graphs are properly labeled, that you show any shifts in those curves, and that you indicate the initial and final equilibrium points.

b. Can we use this information to be certain whether the equilibrium quantity of recycled plastic will increase or decrease?

4.7 The demand for typical Christmas cakes such as *pandoro* and *panettone* is very high before and during the Christmas season. 4.9 The European Union (EU) has put a tariff system in place on imports of bananas from Latin America. The rationale behind this tariff system is that the imports of cheap bananas may damage domestic consumption of fresh fruits produced in the EU.

- Is the European legislator assuming that fresh fruit and bananas are substitutes or complements? Briefly explain.
- If a tariff on bananas acts as an increase in the cost of supplying bananas in the EU, use two demand and supply graphs to show the effects of the introduction of the tariff system. One graph should show the effect on the banana market in the EU, and the other graph should show the effect on the fresh fruit market in the EU. Be sure to label the change in equilibrium price and quantity in each market and any shifts in the demand and supply curves.

4.10 According to one news story, the cost of producing 4K televisions has been declining. According to a second story, many people have switched from watching programs on television sets to watching them on smartphones, tablets, or laptops. After reading these news stories, a student argues: “From this information, we know that the price of 4K televisions will fall, but we don’t know whether the quantity of television sets sold will increase or decrease.” Is the student’s analysis correct? 4.11 Historically, the production of many perishable foods, such as dairy products, was highly seasonal. As the supply of those products fluctuated, prices tended to fluctuate tremendously—typically by 25 to 50 percent or more—over the course of the year. One effect of mechanical refrigeration, which was commercialized on a large scale in the last decade of the nineteenth century, was that suppliers could store perishable foods from one season to the next. Economists have estimated that as a result of refrigerated storage, wholesale prices rose by roughly 10 percent during peak supply periods, while they fell by almost the same amount during the off season. Use a demand and supply graph for each season to illustrate how refrigeration affected the market for perishable food.

4.12 Suppose an unknown parasite has been damaging the corn crops grown by a farmer. However, it seems that no one has adequate knowledge to be able to devise a remedy for this problem. How would you expect this event to affect the equilibrium price and quantity of corn in the following year?

4.13 (Related to the Don’t Let This Happen to You on page 153) A student writes the following: “When the producer of a good lowers its price, the demand curve shifts rightward and the price goes back to the initial level.” Briefly explain.

4.14 (Related to the Don’t Let This Happen to You on page 153) A student was asked to draw a demand and supply graph to illustrate the effect on the market for smartwatches of a fall in the price of displays used in smartwatches, holding everything else constant. She drew the following graph and explained it as follows:

Displays are an input to smartwatches, so a fall in the price of displays will cause the supply curve for smartwatches to shift to the right

(from S_1 to S_2). Because this shift in the supply curve results in a lower price (P_2), consumers will want to buy more smartwatches, and the demand curve will shift to the right (from D_1 to D_2). We know that more smartwatches will be sold, but we can't be sure whether the price of smartwatches will rise or fall. That depends on whether the supply curve or the demand curve has shifted farther to the right. I assume that the effect on supply is greater than the effect on demand, so I show the final equilibrium price (P_3) as being lower than the initial equilibrium price (P_1).

Explain whether you agree with the student's analysis. Be careful to explain exactly what—if anything—you find wrong with her analysis.

4.15 Following are four graphs and four market scenarios, each of which would cause either a movement along the supply curve for Volkswagen Golf or a shift of the supply curve. Match each scenario with the appropriate graph.

- a. A decrease in the supply of Ford Focus
- b. A drop in the average household income in the EU from €52,000 to €50,000
- c. An improvement in car production technology
- d. An increase in the prices of steel and plastic

4.16 Proposals have been made to increase government regulation of firms providing childcare services by, for instance, setting education requirements for childcare workers. Suppose that these regulations increase the quality of childcare and cause the demand for childcare services to increase. At the same time, assume that complying with the new government regulations increases the costs of firms providing childcare services. The Sharing Economy, Phone Apps, and Rent Control

The role of markets is to bring together buyers and sellers. A market can be a physical place, like a retail mall, or a virtual place, like eBay. What if you need to rent an apartment or a bicycle for only a day or a week? Internet startup companies have created rental markets for short-term use of products including apartments, cars, boats, and bicycles. For example, people who download the Airbnb app can search for short-term room rentals in 30,000 cities in 192 countries. The suppliers in this market are typically people who want to earn extra money by renting their house, apartment, or sometimes just a single room for a few days. The *Economist* magazine has referred to the rapid increase in the number of people using peer-to-peer rental sites as the rise of the “sharing economy.”

More than 25 million people had rented rooms on Airbnb by 2015. Despite this success, Airbnb has run into problems, particularly in cities that have rent control regulations. In New York, San Francisco, Los Angeles, and nearly 200 smaller cities in the United States, apartments are subject to rent control by the local government. Rent control puts a legal limit on the rent that landlords can charge for an apartment. Supporters of rent control argue that it is necessary to preserve affordable apartments in cities where equilibrium market rents would be above what middle- and lower-income people are willing and able to pay. But, as we will see in this

chapter, rent controls cause a shortage of apartments and give people an incentive to list their apartments on sites like Airbnb at rents far above the controlled rents. In San Francisco, landlords complain that some high-income renters have moved out of the city but have kept their rent-controlled apartments in order to rent them using the apartment-sharing sites. In New York, where it is against the law to rent a room in an apartment for less than 30 days, officials struggled with how to enforce the rules despite Airbnb’s great popularity.

Some observers argue that the difficulty governments face regulating peer-to-peer rental sites will make it impossible to enforce rent control rules. In San Francisco, where an estimated 1,300 people a night were renting rooms through Airbnb, supporters and opponents were battling over attempts to further regulate the site, including imposing fines of \$1,000 a day on anyone violating existing rental regulations.

AN INSIDE LOOK AT POLICY on **page 190** explores why government officials in Malibu, California, imposed a tax on short-term rentals of apartments booked through Airbnb.

Economics in Your Life

Does Rent Control Make It Easier for You to Find an Affordable Apartment?

Suppose you have job offers in two cities. One factor in deciding which job to accept is whether you can find an affordable apartment. If one city has rent control, are you more likely to find an affordable apartment in that city, or would you be better off looking for an apartment in a city without rent control? As you read the chapter, try to answer this question. You can check your answer against the one we provide on **page 189** at the end of this chapter.

In a competitive market, the price adjusts to ensure that the quantity demanded equals the quantity supplied. Stated another way, in equilibrium, every consumer willing to pay the market price is able to buy as much of the product as the consumer wants, and every firm willing to accept the market price can sell as much as it wants. Consumers would naturally prefer to pay a lower price, and sellers would prefer to receive a higher price. Normally, consumers and firms have no choice but to accept the equilibrium price if they wish to participate in the market.

Occasionally, however, consumers or firms persuade the government to intervene to try to lower or raise the market price of a good or service:

Price ceiling A legally determined maximum price that sellers may charge.

Price floor A legally determined minimum price that sellers may receive.

- Consumers sometimes succeed in having the government impose a **price ceiling**, which is a legally determined maximum price that sellers may charge. Rent control is an example of a price ceiling.
- Firms sometimes succeed in having the government impose a **price floor**, which is a legally determined minimum price that sellers may receive. In markets for farm products such as milk, the government has been setting price floors that are above the equilibrium market price since the 1930s.

Another way the government intervenes in markets is by imposing taxes. The government relies on the revenue raised from taxes to finance its operations. But taxes also affect the decisions that consumers and firms make.

Each of these government interventions has predictable negative consequences for economic efficiency. Economists have developed the concepts of *consumer surplus*, *producer surplus*, and *deadweight loss* to help policymakers and voters analyze the economic effects of price ceilings, price floors, and taxes.

4.1

Consumer Surplus and Producer Surplus

LEARNING OBJECTIVE: Distinguish between the concepts of consumer surplus and producer surplus.

Consumer surplus measures the dollar benefit consumers receive from buying goods or services in a particular market. Producer surplus measures the dollar benefit firms receive from selling goods or services in a particular market. Economic surplus in a market is the sum of consumer surplus and producer surplus. As we will see, *when the government imposes a price ceiling or a price floor, the amount of economic surplus in a market is reduced*; in other words, price ceilings and price floors reduce the total benefit to consumers and firms from buying and selling in a market. To understand why this is true, we need to understand how consumer surplus and producer surplus are determined.

Consumer Surplus

Consumer surplus The difference between the highest price a consumer is willing to pay for a good or service and the actual price the consumer pays.

Consumer surplus is the difference between the highest price a consumer is willing to pay for a good or service and the actual price the consumer pays. Suppose you are in Walmart, and you see a DVD of *Star Wars: The Force Awakens* on the shelf. The DVD doesn't have a price sticker, so you take it to the register to check the price. As you walk to the register, you think to yourself that \$18 is the highest price you would be willing to pay. At the register, you find out that the price is actually \$12, so you buy the DVD. Your consumer surplus in this example is \$6: the difference between the \$18 you were willing to pay and the \$12 you actually paid.

We can use the demand curve to measure the total consumer surplus in a market. Demand curves show the willingness of consumers to purchase a product at different prices. Consumers are willing to purchase a product up to the point where the marginal benefit of consuming a product is equal to its price. The **marginal benefit** is the additional benefit to a consumer from consuming one more unit of a good or service. As a simple example, suppose there are only four consumers in the market for chai tea: Theresa, Tom, Terri, and Tim. Because these four consumers have different tastes for

Figure 4.1

Deriving the Demand Curve for Chai Tea

With four consumers in the market for chai tea, the demand curve is determined by the highest price each consumer is willing to pay. At prices above \$6, no tea is sold because \$6 is the highest price any consumer is willing to pay. At prices of \$3 and below, each of the four consumers is willing to buy a cup of tea.

tea and different incomes, the marginal benefit each of them receives from consuming a cup of tea will be different. Therefore, the highest price each is willing to pay for a cup of tea is also different. In Figure 4.1, the information from the table is used to construct a demand curve for chai tea. At prices above \$6 per cup, no tea is sold because \$6 is the highest price any of the consumers is willing to pay. At a price of \$5, both Theresa and Tom are willing to buy tea, so two cups are sold. At prices of \$3 and below, all four consumers are willing to buy tea, and four cups are sold.

Suppose the market price of tea is \$3.50 per cup. As Figure 4.2 shows, the demand curve allows us to calculate the total consumer surplus in this market. Panel (a) shows

(a) Consumer surplus with a market price of \$3.50

(b) Consumer surplus with a market price of \$3.00

Figure 4.2 Measuring Consumer Surplus

Panel (a) shows the consumer surplus for Theresa, Tom, and Terri when the price of tea is \$3.50 per cup. Theresa's consumer surplus is equal to the area of rectangle A and is the difference between the highest price she would pay—which is \$6—and the market price of \$3.50. Tom's consumer surplus is equal to the area of rectangle B, and Terri's consumer surplus

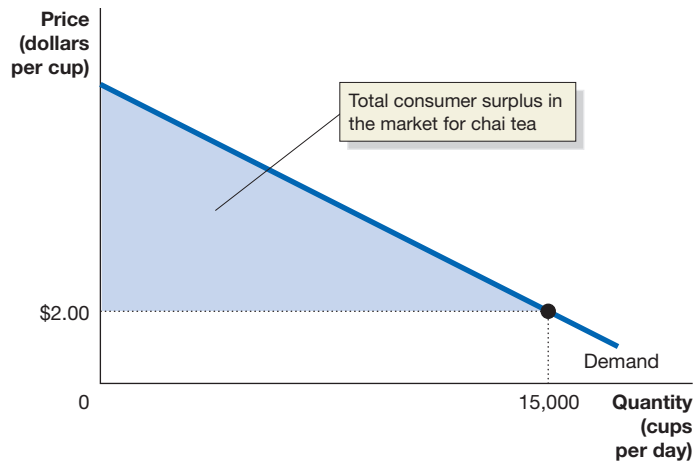

is equal to the area of rectangle C. Total consumer surplus in this market is equal to the sum of the areas of rectangles A, B, and C, or the total area below the demand curve and above the market price. In panel (b), consumer surplus increases by the dark blue area as the market price declines from \$3.50 to \$3.00.

MyEconLab Animation

Figure 4.3

Total Consumer Surplus in the Market for Chai Tea

The demand curve shows that most buyers of chai tea would have been willing to pay more than the market price of \$2.00. For each buyer, consumer surplus is equal to the difference between the highest price he or she is willing to pay and the market price actually paid. Therefore, the total amount of consumer surplus in the market for chai tea is equal to the area below the demand curve and above the market price. Consumer surplus represents the benefit to consumers in excess of the price they paid to purchase a product.

that the highest price Theresa is willing to pay is \$6, but because she pays only \$3.50, her consumer surplus is \$2.50 (shown by the area of rectangle A). Similarly, Tom's consumer surplus is \$1.50 (rectangle B), and Terri's consumer surplus is \$0.50 (rectangle C). Tim is unwilling to buy a cup of tea at a price of \$3.50, so he doesn't participate in this market and receives no consumer surplus. In this simple example, the total consumer surplus is equal to $\$2.50 + \$1.50 + \$0.50 = \4.50 (or the sum of the areas of rectangles A, B, and C). Panel (b) shows that a lower price will increase consumer surplus. If the price of tea falls from \$3.50 per cup to \$3.00, Theresa, Tom, and Terri each receive \$0.50 more in consumer surplus (shown by the dark blue areas), so the total consumer surplus in the market rises to \$6.00. Tim now buys a cup of tea but doesn't receive any consumer surplus because the price is equal to the highest price he is willing to pay. In fact, Tim is indifferent between buying the cup or not—his well-being is the same either way.

The market demand curves shown in Figures 4.1 and 4.2 do not look like the typical smooth demand curve because in this case we have only a small number of consumers, each consuming a single cup of tea. With many consumers, the market demand curve for chai tea will have the normal smooth shape shown in Figure 4.3. In this figure, the quantity demanded at a price of \$2.00 is 15,000 cups per day. We can calculate total consumer surplus in Figure 4.3 the same way we did in Figures 4.1 and 4.2—by adding up the consumer surplus received on each unit purchased. Once again, we can draw an important conclusion: *The total amount of consumer surplus in a market is equal to the area below the demand curve and above the market price.* Consumer surplus is shown as the shaded area in Figure 4.3 and represents the benefit to consumers in excess of the price they paid to purchase a product—in this case, chai tea.

The Consumer Surplus from Broadband Internet Service

Consumer surplus allows us to measure the benefit consumers receive in excess of the price they pay to purchase a product.

Shane Greenstein of Northwestern University and Ryan McDevitt of the University of Rochester estimated the consumer surplus that households receive from subscribing to broadband Internet service. To carry out the analysis, they estimated the demand curve for broadband Internet service and then computed the shaded area shown in the following graph.

In the year they analyzed, 47 million consumers paid an average price of \$36 per month to subscribe to a broadband Internet service. The demand curve shows the marginal benefit consumers receive from subscribing to a broadband Internet service rather than using dialup or doing without access to the Internet. The area below the demand curve and above the \$36 price line represents the difference between the price consumers

would have paid rather than do without broadband service and the \$36 they did pay. The shaded area on the graph represents the total consumer surplus in the market for broadband Internet service. Greenstein and McDevitt estimate that the value of this area is \$890.4 million. This value is one month's benefit to the consumers who subscribe to a broadband Internet service.

Producer Surplus

Just as demand curves show the willingness of consumers to buy a product at different prices, supply curves show the willingness of firms to supply a product at different prices. The willingness to supply a product depends on the cost of producing it. Firms will supply an additional unit of a product only if they receive a price equal to the additional cost of producing that unit. **Marginal cost** is the additional cost to a firm of producing one more unit of a good or service. Consider the marginal cost to the firm Heavenly Tea of producing one more cup of tea: In this case, the marginal cost includes the ingredients to make the tea and the wages paid to the worker preparing the tea. Often, the marginal cost of producing a good increases as more of the good is produced during a given period of time. Increasing marginal cost is the key reason that supply curves are upward sloping.

Panel (a) of Figure 4.4 shows Heavenly Tea's producer surplus. For simplicity, we show Heavenly producing only a small quantity of tea. The figure shows that Heavenly's marginal cost of producing the first cup of tea is \$1.25, its marginal cost of producing the second cup is \$1.50, and so on. The marginal cost of each cup of tea is the lowest price Heavenly is willing to accept to supply that cup. The supply curve, then, is also a marginal cost curve. Suppose the market price of tea is \$2.00 per cup. On the first cup of tea, the price is \$0.75 higher than the lowest price that Heavenly is willing to accept. **Producer surplus** is the difference between the lowest price a firm would be willing to accept for a good or service and the price it actually receives. Therefore, Heavenly's producer surplus on the first cup is \$0.75 (shown by the area of rectangle A), its producer surplus on the second cup is \$0.50 (rectangle B), and its producer surplus on the third cup is \$0.25 (rectangle C). Heavenly will not be willing to supply the fourth cup because the marginal cost of producing it is greater than the market price. Heavenly Tea's total producer surplus is equal to $\$0.75 + \$0.50 + \$0.25 = \1.50 (or the sum of the areas of rectangles A, B, and C). A higher price will increase producer surplus. For example, if the market price of chai tea rises from \$2.00 to \$2.25, Heavenly Tea's producer surplus

Figure 4.4 Measuring Producer Surplus

Panel (a) shows Heavenly Tea's producer surplus. The lowest price Heavenly Tea is willing to accept to supply a cup of tea is equal to its marginal cost of producing that cup. When the market price of tea is \$2.00, Heavenly receives producer surplus of \$0.75 on the first cup (the area of rectangle A), \$0.50 on the second cup (rectangle B), and \$0.25 on the third cup

(rectangle C). In panel (b), the total amount of producer surplus tea sellers receive from selling chai tea can be calculated by adding up for the entire market the producer surplus received on each cup sold. In the figure, total producer surplus is equal to the shaded area above the supply curve and below the market price.

will increase from \$1.50 to \$2.25. (Make sure you understand how the new level of producer surplus was calculated.)

The supply curve shown in panel (a) of Figure 4.4 does not look like the typical smooth supply curve because we are looking at a single firm producing only a small quantity of tea. With many firms, the market supply curve for chai tea will have the normal smooth shape shown in panel (b) of Figure 4.4. In panel (b), the quantity supplied at a price of \$2.00 is 15,000 cups per day. We can calculate total producer surplus in panel (b) the same way we did in panel (a): by adding up the producer surplus received on each cup sold. Therefore, *the total amount of producer surplus in a market is equal to the area above the market supply curve and below the market price*. The total producer surplus tea sellers receive from selling chai tea is shown as the shaded area in panel (b) of Figure 4.4.

MyEconLab Concept Check

What Consumer Surplus and Producer Surplus Measure

We have seen that consumer surplus measures the benefit to consumers from participating in a market, and producer surplus measures the benefit to producers from participating in a market. It is important to be clear about what these concepts are measuring. In a sense, consumer surplus measures the *net* benefit to consumers from participating in a market rather than the *total* benefit. That is, if the price of a product were zero, the consumer surplus in a market would be all of the area under the demand curve. When the price is not zero, consumer surplus is the area below the demand curve and above the market price. So, consumer surplus in a market is equal to the total benefit consumers receive minus the total amount they must pay to buy the good or service.

Similarly, producer surplus measures the *net* benefit received by producers from participating in a market. If producers could supply a good or service at zero cost, the producer surplus in a market would be all of the area below the market price. When cost is not zero, producer surplus is the area below the market price and above the supply curve. So, producer surplus in a market is equal to the total dollar amount firms receive from consumers minus the cost of producing the good or service.

4.2

The Efficiency of Competitive Markets

LEARNING OBJECTIVE: Explain the concept of economic efficiency.

Recall that a *competitive market* is a market with many buyers and many sellers. An important advantage of the market system is that it results in efficient economic outcomes. But what does *economic efficiency* mean? The concepts we have developed so far in this chapter give us two ways to think about the economic efficiency of competitive markets. We can think in terms of marginal benefit and marginal cost. We can also think in terms of consumer surplus and producer surplus. As we will see, these two approaches lead to the same outcome, but using both can increase our understanding of economic efficiency.

Marginal Benefit Equals Marginal Cost in Competitive Equilibrium

Figure 4.5 again shows the market for chai tea. Recall that the demand curve shows the marginal benefit received by consumers, and the supply curve shows the marginal cost of production. For this market to achieve economic efficiency, the marginal benefit from the last unit sold should equal the marginal cost of production. The figure shows that this equality occurs at competitive equilibrium where 15,000 cups per day are produced and marginal benefit and marginal cost are both equal to \$2.00. This outcome is economically efficient because every cup of chai tea has been produced where the marginal benefit to buyers is greater than or equal to the marginal cost to producers.

To further understand why the level of output at competitive equilibrium is efficient, consider what the situation would be if output were at a different level. Suppose that output of chai tea were 14,000 cups per day. Figure 4.5 shows that at this level of output, the marginal benefit from the last cup sold is \$2.20, while the marginal cost is only \$1.80. This level of output is not efficient because 1,000 more cups could be produced for which the additional benefit to consumers would be greater than the additional cost of production. Consumers would willingly purchase those cups, and tea sellers would willingly supply them, making both consumers and sellers better off. Similarly, if the output of chai tea were 16,000 cups per day, the marginal cost of the 16,000th cup is \$2.20, while the marginal benefit is only \$1.80. Tea sellers would only be willing to supply this cup at a price of \$2.20, which is \$0.40 higher than consumers would be willing to pay. In fact, consumers would not be willing to pay the price tea sellers would need to receive for any cup beyond the 15,000th.

To summarize: *Equilibrium in a competitive market results in the economically efficient level of output, at which marginal benefit equals marginal cost.*

Marginal Benefit Equals Marginal Cost Only at Competitive Equilibrium

In a competitive market, equilibrium occurs at a quantity of 15,000 cups and a price of \$2.00 per cup, where marginal benefit equals marginal cost. This level of output is economically efficient because every cup has been produced for which the marginal benefit to buyers is greater than or equal to the marginal cost to producers.

Economic Surplus Equals the Sum of Consumer Surplus and Producer Surplus

The economic surplus in a market is the sum of the blue area, representing consumer surplus, and the red area, representing producer surplus.

Economic Surplus

Economic surplus in a market is the sum of consumer surplus and producer surplus. In a competitive market, with many buyers and sellers and no government restrictions, economic surplus is at a maximum when the market is in equilibrium. To see this point, let's look at the market for chai tea shown again in Figure 4.6. The consumer surplus in this market is the blue area below the demand curve and above the line indicating the equilibrium price of \$2.00. The producer surplus is the red area above the supply curve and below the price line.

Deadweight Loss

To show that economic surplus is maximized at equilibrium, consider a situation in which the price of chai tea is *above* the equilibrium price, as shown in Figure 4.7. At a

	At Competitive Equilibrium	At a Price of \$2.20
Consumer Surplus	A + B + C	A
Producer Surplus	D + E	B + D
Deadweight Loss	None	C + E

MyEconLab Animation

Figure 4.7 When a Market Is Not in Equilibrium, There Is a Deadweight Loss

Economic surplus is maximized when a market is in competitive equilibrium. When a market is not in equilibrium, there is a deadweight loss. For example, when the price of chai tea is \$2.20 instead of \$2.00, consumer surplus declines from an amount equal to

the sum of areas A, B, and C to just area A. Producer surplus increases from the sum of areas D and E to the sum of areas B and D. At competitive equilibrium, there is no deadweight loss. At a price of \$2.20, there is a deadweight loss equal to the sum of triangles C and E.

price of \$2.20 per cup, the number of cups consumers are willing to buy per day falls from 15,000 to 14,000. At competitive equilibrium, consumer surplus is equal to the sum of areas A, B, and C. At a price of \$2.20, fewer cups are sold at a higher price, so consumer surplus declines to just the area of A. At competitive equilibrium, producer surplus is equal to the sum of areas D and E. At the higher price of \$2.20, producer surplus changes to be equal to the sum of areas B and D. The sum of consumer and producer surplus—economic surplus—has been reduced to the sum of areas A, B, and D. Notice that this sum is less than the original economic surplus by an amount equal to the sum of triangles C and E. Economic surplus has declined because at a price of \$2.20, all the cups between the 14,000th and the 15,000th, which would have been produced in competitive equilibrium, are not being produced. These “missing” cups are not providing any consumer or producer surplus, so economic surplus has declined. The reduction in economic surplus resulting from a market not being in competitive equilibrium is called the **deadweight loss**. In the figure, deadweight loss is equal to the sum of the triangles C and E.

MyEconLab Concept Check

Deadweight loss The reduction in economic surplus resulting from a market not being in competitive equilibrium.

Economic Surplus and Economic Efficiency

Consumer surplus measures the benefit to consumers from buying a particular product, such as chai tea. Producer surplus measures the benefit to firms from selling a particular product. Therefore, economic surplus—which is the sum of the benefit to firms plus the benefit to consumers—is the best measure we have of the benefit to society from the production of a particular good or service. Economic surplus gives us a second way of characterizing the economic efficiency of a competitive market: *Equilibrium in a competitive market results in the greatest amount of economic surplus, or total net benefit to society, from the production of a good or service.* Anything that causes the market for a good or service not to be in competitive equilibrium reduces the total benefit to society from the production of that good or service.

Now we can give a more general definition of *economic efficiency* in terms of our two approaches: **Economic efficiency** is a market outcome in which the marginal benefit to consumers of the last unit produced is equal to its marginal cost of production and in which the sum of consumer surplus and producer surplus is at a maximum.

MyEconLab Concept Check

Economic efficiency A market outcome in which the marginal benefit to consumers of the last unit produced is equal to its marginal cost of production and in which the sum of consumer surplus and producer surplus is at a maximum.

4.3

Government Intervention in the Market: Price Floors and Price Ceilings

LEARNING OBJECTIVE: Explain the economic effect of government-imposed price floors and price ceilings.

Notice that we have *not* concluded that every *individual* is better off if a market is at competitive equilibrium. We have concluded only that economic surplus, or the *total* net benefit to society, is greatest at competitive equilibrium. Any individual producer would rather receive a higher price, and any individual consumer would rather pay a lower price, but usually producers can sell and consumers can buy only at the competitive equilibrium price.

Producers or consumers who are dissatisfied with the competitive equilibrium price can lobby the government to legally require that a different price be charged. In the United States, the government only occasionally overrides the market outcome by setting prices. When the government does intervene, it can attempt to aid either sellers by requiring that a price be above equilibrium—a price floor—or buyers by requiring that a price be below equilibrium—a price ceiling. To affect the market outcome, the government must set a legal price floor that is above the equilibrium price or set a legal price ceiling that is below the equilibrium price. Otherwise, the price ceiling or price floor will not be *binding* on buyers and sellers. We can use the concepts of consumer surplus, producer surplus, and deadweight loss to understand more clearly why price floors and price ceilings reduce economic efficiency.

Price Floors: Government Policy in Agricultural Markets

The Great Depression of the 1930s was the worst economic disaster in U.S. history, affecting every sector of the economy. Many farmers could sell their products only at very low prices, so they convinced the federal government to set price floors for many agricultural products, such as wheat and corn. Government intervention in agriculture—often referred to as the *farm program*—has continued ever since. To understand how a price floor in an agricultural market works, suppose that the equilibrium price in the wheat market is \$6.50 per bushel, but the government decides to set a price floor of \$8.00 per bushel. As Figure 4.8 shows, the price of wheat rises from \$6.50 to \$8.00, and the quantity of wheat sold falls from 2.0 billion bushels per year to 1.8 billion. Initially, suppose that production of wheat also falls to 1.8 billion bushels.

The producer surplus received by wheat farmers increases by an amount equal to the area of rectangle A and decreases by an amount equal to the area of triangle C. (This is the same result we saw in the market for chai tea in Figure 4.7.) The area of rectangle A represents a transfer from consumer surplus to producer surplus. The total fall in consumer surplus is equal to the sum of the areas of rectangle A and triangle B. Wheat farmers benefit from this program, but consumers lose. There is also a deadweight loss equal to the areas of triangles B and C because economic efficiency declines as the price floor reduces the amount of economic surplus in the market for wheat. In other words, the price floor has caused the marginal benefit of the last bushel of wheat to be greater than the marginal cost of producing it. We can conclude that a price floor reduces economic efficiency.

We assumed initially that farmers reduce their production of wheat to the amount consumers are willing to buy. In fact, as Figure 4.8 shows, a price floor will cause the quantity of wheat that farmers want to supply to increase from 2.0 billion to 2.2 billion bushels. Because the higher price also reduces the amount of wheat consumers want to buy, the result is a surplus of 0.4 billion bushels of wheat (the 2.2 billion bushels supplied minus the 1.8 billion demanded).

MyEconLab Animation

Figure 4.8 The Economic Effect of a Price Floor in the Wheat Market

If wheat farmers convince the government to impose a price floor of \$8.00 per bushel, the amount of wheat sold will fall from 2.0 billion bushels per year to 1.8 billion. If we assume that farmers produce 1.8 billion bushels, producer surplus then increases by rectangle A—which is transferred from consumer surplus—and falls by triangle C.

Consumer surplus declines by rectangle A plus triangle B. There is a deadweight loss equal to triangles B and C, representing the decline in economic efficiency due to the price floor. In reality, a price floor of \$8.00 per bushel will cause farmers to expand their production from 2.0 billion to 2.2 billion bushels, resulting in a surplus of wheat.

The federal government's farm programs have often resulted in large surpluses of wheat and other agricultural products. In response, the government has usually either bought the surplus food or paid farmers to restrict supply by taking some land out of cultivation. Because both of these options are expensive, Congress passed the Freedom to Farm Act of 1996. The intent of the act was to phase out price floors and government purchases of surpluses and return to a free market in agriculture. To allow farmers time to adjust, the federal government began paying farmers *subsidies*, or cash payments based on the number of acres planted. Although the subsidies were originally scheduled to be phased out, Congress has passed additional farm bills that have resulted in the continuation of subsidies requiring substantial federal government spending. In 2015, the Congressional Budget Office estimated that the farm program would result in federal spending of more than \$145 billion over the following 10 years.

Price Floors in Labor Markets: The Debate over Minimum Wage Policy

The minimum wage may be the most controversial “price floor.” Supporters see the minimum wage as a way of raising the incomes of low-skilled workers. Opponents argue that it results in fewer jobs and imposes large costs on small businesses.

Since 2009, the national minimum wage as set by Congress has been \$7.25 per hour for most occupations. It is illegal for an employer to pay less than this wage in these occupations. Although only about 4 percent of workers in the United States earn the minimum wage or less, many people are concerned that workers who receive the minimum wage or a wage a little above the minimum are not earning a “living wage” that would allow them to escape from poverty. In 2015, President Barack Obama proposed raising the minimum wage in a series of steps to \$10.10 per hour. Some members of Congress introduced legislation to raise it to \$12 per hour. Several cities and states are increasing their minimum wage to as high as \$15 per hour. Protests in a number of cities were intended to pressure fast-food restaurants and other employers to voluntarily raise the minimum wage they paid to \$15 per hour.

For many workers, the legal minimum wage is irrelevant because it is well below the wage employers are voluntarily willing to pay them. But for some low-skilled workers—such as restaurant workers—the minimum wage is above the wage they would otherwise receive. The following figure shows the effect of the minimum wage on employment in the market for low-skilled labor.

Without a minimum wage, the equilibrium wage would be W_1 and the number of workers hired would be L_1 . With a minimum wage set above the equilibrium wage, the number of workers employers demand declines from L_1 to L_2 , and the quantity of labor supplied increases to L_3 , leading to a surplus of workers unable to find jobs equal to $L_3 - L_2$. The quantity of labor supplied increases because the higher wage attracts more people to work. For instance, some teenagers may decide that working after school is worthwhile at the minimum wage of \$7.25 per hour but would not be worthwhile at a lower wage.

This analysis is very similar to our analysis of the wheat market in Figure 4.8. Just as a price floor in the wheat market leads to less wheat being consumed, a price floor in the labor market should lead to fewer workers being hired. Views differ sharply among economists, however, concerning how large a reduction in employment the minimum wage causes. The U.S. Congressional Budget Office (CBO) estimates that raising the minimum wage to \$10.10 per hour would result in a decline in employment of 500,000 workers. Some economists believe that the effects of the minimum wage on employment are far smaller, however. For instance, David Card of the University of California, Berkeley, and Alan Krueger of Princeton University conducted a study of fast-food restaurants in New Jersey and Pennsylvania. Their study indicated that the effect of past minimum wage increases on employment has been very small. This study has been controversial, and other economists have examined similar data and come to the different conclusion that the minimum wage leads to a significant decrease in employment.

Whatever the extent of employment losses from the minimum wage, because it is a price floor, it will cause a deadweight loss, just as a price floor in the wheat market does. Therefore, many economists favor alternative policies for attaining the goal of raising the incomes of low-skilled workers. One policy many economists support is the *earned income tax credit*, which reduces the amount of tax that low-income wage earners would otherwise pay to the federal government. Workers with very low incomes who do not owe any tax receive a payment from the government. Unlike with the minimum wage, the earned income tax credit can increase the incomes of low-skilled workers without reducing employment. The earned income tax credit also places a lesser burden on the small businesses that employ many low-skilled workers and may cause a smaller loss of economic efficiency.

Price Ceilings: Government Rent Control Policy in Housing Markets

Support for governments setting price floors typically comes from sellers, and support for governments setting price ceilings typically comes from consumers. For example, when there is a sharp increase in gasoline prices, proposals are often made for the government to impose a price ceiling on the market for gasoline. As we saw in the chapter opener, a number of cities impose rent control, which puts a ceiling on the maximum rent that landlords can charge for an apartment. Figure 4.9 shows the market for apartments in a city that has rent control.

MyEconLab Animation

Figure 4.9 The Economic Effect of a Rent Ceiling

Without rent control, the equilibrium rent is \$2,500 per month. At that price, 2,000,000 apartments would be rented. If the government imposes a rent ceiling of \$1,500 per month, the quantity of apartments supplied decreases to 1,900,000, and the quantity of

apartments demanded increases to 2,100,000, resulting in a shortage of 200,000 apartments. Producer surplus equal to the area of rectangle A is transferred from landlords to renters, and there is a deadweight loss equal to the areas of triangles B and C.

Without rent control, the equilibrium rent would be \$2,500 per month, and 2,000,000 apartments would be rented. With a maximum legal rent of \$1,500 per month, landlords reduce the quantity of apartments supplied to 1,900,000. The fall in the quantity of apartments supplied can be the result of landlords converting some apartments into offices, selling some off as condominiums, or converting some small apartment buildings into single-family homes. Over time, landlords may even abandon some apartment buildings. At one time in New York City, rent control resulted in landlords abandoning whole city blocks because they were unable to cover their costs with the rents the government allowed them to charge. In London, when rent controls were applied to rooms and apartments located in a landlord's own home, the quantity of these apartments supplied decreased by 75 percent.

In Figure 4.9, with the rent ceiling of \$1,500 per month, the quantity of apartments demanded rises to 2,100,000, resulting in a shortage of 200,000 apartments. Consumer surplus increases by rectangle A and falls by triangle B. Rectangle A would have been part of producer surplus if rent control were not in place. With rent control, it is part of consumer surplus. Rent control causes the producer surplus landlords receive to fall by rectangle A plus triangle C. Triangles B and C represent the deadweight loss, which results from rent control reducing the amount of economic surplus in the market for apartments. Rent control has caused the marginal benefit of the last apartment rented to be greater than the marginal cost of supplying it. We can conclude that a price ceiling, such as rent control, reduces economic efficiency. The appendix to this chapter shows how we can make quantitative estimates of the deadweight loss and provides an example of the changes in consumer surplus and producer surplus that can result from rent control.

Renters as a group benefit from rent controls—total consumer surplus is larger—but landlords lose. Because of the deadweight loss, the total loss to landlords is greater than the gain to renters. Notice also that although renters as a group benefit, the number of renters is reduced, so some renters are made worse off by rent controls because they are unable to find an apartment at the legal rent.

Don't Let This Happen to You

Don't Confuse "Scarcity" with "Shortage"

At first glance, the following statement seems correct: "There is a shortage of every good that is scarce." In everyday conversation, we describe a good as "scarce" if we have trouble finding it. For instance, if you are looking for a gift for a child, you might call the latest hot toy "scarce" if you are willing to buy it at its listed price but can't find it online or in any store. But recall that economists have a broader definition of *scarce*. In the economic sense, almost

everything—except undesirable things like garbage—is scarce. A shortage of a good occurs only if the quantity demanded is greater than the quantity supplied at the current price. Therefore, the preceding statement—"There is a shortage of every good that is scarce"—is incorrect. In fact, there is no shortage of most scarce goods.

Black market A market in which buying and selling take place at prices that violate government price regulations.

Black Markets and Peer-to-Peer Sites

When governments regulate prices by enacting price ceilings or price floors, buyers and sellers often find a way around the regulations. As a result, renters may be worse off and landlords may be better off than Figure 4.9 makes it seem. We have assumed that renters and landlords actually abide by the price ceiling, but sometimes they don't. Because rent control leads to a shortage of apartments, renters who would otherwise not be able to find apartments have an incentive to offer landlords rents *above* the legal maximum. The result is a **black market** in which buying and selling take place at prices that violate government price regulations.

Online peer-to-peer rental sites like Airbnb have provided landlords and tenants another way to avoid rent controls. Landlords can use these sites to convert a regular yearly rental into a series of short-term rentals for which they can charge above the legal maximum rent. Tenants can also use the sites to make a profit from rent controls. As we saw in the chapter opener, in San Francisco, some tenants moved out of the city but kept their rent-controlled apartments and rented them using peer-to-peer rental sites. Both San Francisco and New York have taken actions against peer-to-peer rental sites because some government officials believe the sites undermine rent control. Both cities have laws that prohibit landlords from renting apartments for less than 30 days. San Francisco also announced that anyone renting rooms through Airbnb and similar sites must pay the city's 14 percent hotel tax.

Some government officials in both cities, however, were reluctant to take actions that might limit the growth of the sharing economy of peer-to-peer rental sites. The sharing economy has the potential to improve economic efficiency and make available to consumers goods, such as cars, bikes, boats, and apartments, at lower prices. When cities have rent control laws, though, peer-to-peer sites perform a somewhat different function, making apartments available at rents higher than the legal price ceiling—apartments that renters might otherwise have difficulty finding because of the shortage caused by rent control. It remains to be seen whether local policymakers can resolve the conflict between putting legal ceilings on rents and encouraging peer-to-peer sites to operate in their cities.

What's the Economic Effect of a Black Market in Renting Apartments?

In many cities that have rent controls, such as New York and San Francisco, the actual rents paid can be much higher than the legal maximum. Because rent controls cause a shortage of apartments, desperate tenants are often willing to pay landlords rents that are higher than the law allows, perhaps by writing a check for the legally allowed rent and paying an additional amount in cash. Look again at Figure 4.9

on page 179. Suppose that competition among tenants results in the black market rent rising to \$3,500 per month. At this rent, tenants demand 1,900,000 apartments. Draw a graph showing the market for apartments and compare this situation with the one shown in Figure 4.9. Be sure to note any differences in consumer surplus, producer surplus, and deadweight loss.

Solving the Problem

Step 1: Review the chapter material. This problem is about price controls in the market for apartments, so you may want to review the section “Price Ceilings: Government Rent Control Policy in Housing Markets,” which begins on page 178.

Step 2: Draw a graph similar to Figure 4.9, with the addition of the black market price.

Step 3: Analyze the changes from Figure 4.9. The black market rent is now \$3,500 per month—even higher than the original competitive equilibrium rent shown in Figure 4.9. So, consumer surplus declines by an amount equal to the sum of the areas of rectangle A and rectangle E. The remaining consumer surplus is triangle D. Note that rectangle A, which would have been part of consumer surplus without rent control, represents a transfer from renters to landlords. Compared with the situation shown in Figure 4.9, producer surplus has increased by an amount equal to the sum of the areas of rectangles A and E, and consumer surplus has declined by the same amount. Deadweight loss is equal to the sum of the areas of triangles B and C, the same as in Figure 4.9.

Extra Credit: This analysis leads to a surprising result: With an active black market in apartments, rent control may leave renters as a group worse off—with less consumer surplus—than if there were no rent control. There is one more possibility to consider, however. If enough landlords become convinced that they can get away with charging rents above the legal ceiling, the quantity of apartments supplied will increase. Eventually, the market could even end up at the competitive equilibrium, with an equilibrium rent of \$2,500 and equilibrium quantity of 2,000,000 apartments. In that case, the rent control price ceiling becomes nonbinding, not because it was set below the equilibrium price but because it was not legally enforced.

Your Turn: For more practice, do related problem 3.14 on page 196 at the end of this chapter.

MyEconLab Study Plan

Rent controls can also lead to an increase in racial and other types of discrimination. With rent controls, more renters are looking for apartments than there are apartments to rent. Landlords can afford to indulge their prejudices by refusing to rent to people from groups they don't like. In cities without rent controls, landlords face more competition, which makes it more difficult to reject tenants on the basis of irrelevant characteristics, such as race.

The Results of Government Price Controls: Winners, Losers, and Inefficiency

When the government imposes price floors or price ceilings, three important results occur:

- 1. Some people win.** The winners from rent control are the people who are paying less for rent because they live in rent-controlled apartments. Landlords may also gain if they break the law by charging rents above the legal maximum for their rent-controlled apartments, provided that those illegal rents are higher than the competitive equilibrium rents would be.
- 2. Some people lose.** The losers from rent control are the landlords of rent-controlled apartments who abide by the law and renters who are unable to find apartments to rent at the controlled price.
- 3. There is a loss of economic efficiency.** Rent control reduces economic efficiency because fewer apartments are rented than would be rented in a competitive market (refer again to Figure 4.9, on page 179). The resulting deadweight loss measures the decrease in economic efficiency.

Why Is Uber Such a Valuable Company?

In most large cities, including San Francisco, Boston, and New York, you can't legally operate a taxi unless you have a permit from the city government. For example, New York City requires taxi drivers to purchase a medallion issued by the city government. The number of medallions issued is limited, and in recent years, the price of a medallion has sometimes exceeded \$1 million. Clearly, it is very expensive to enter the taxi business in most large cities. City governments also typically regulate the price of taxi rides. Because the price of taxi rides in these cities is usually above its equilibrium level, we know that there is a loss of consumer surplus.

Entrepreneur Travis Kalanick of California founded Uber Technologies in 2009 as an alternative to conventional taxis. The firm's slogan is "Choice is a beautiful thing." Uber is a mobile app that allows users to quickly summon a car—often a luxury car such as a BMW or Cadillac—owned by a driver who signs up with Uber and agrees to meet certain requirements. Anyone in a big city who wants to enter the business of offering rides would find it much easier to sign up with Uber than to obtain the permit necessary to operate a conventional taxi. Uber believes that local regulations governing taxis do not apply to its services.

Uber claims to be adding as many as 20,000 new drivers per month worldwide. Taxi drivers in many cities have protested against Uber because they believe competition from Uber drivers will reduce the profitability of driving a taxi. In New York City, in 2015, the price of taxi medallions had fallen by more than 20 percent. Some New York City taxi drivers predicted that the industry would collapse unless the city government more closely regulated Uber.

Investors have estimated that Uber could have a value of \$50 billion—or more than three times the values of auto rental firms Hertz and Avis combined. A much smaller rival ride-sharing service, Lyft, was valued at \$2.5 billion. Investors expect that Uber and Lyft will be very profitable because they offer consumers lower-priced or more convenient car rides than are available from taxis. Uber and Lyft's high profits depend on the large gap between the regulated price of taxi rides and the equilibrium price.

Some people would rather use their smartphone to order a ride from Uber than use a taxi.

In other words, the high profits show that government regulation of the taxi industry has greatly reduced consumer surplus.

Positive and Normative Analysis of Price Ceilings and Price Floors

Are rent controls, government farm programs, and other price ceilings and price floors bad? As we saw in Chapter 1, questions of this type do not have right or wrong answers. Economists are generally skeptical of government attempts to interfere with competitive market equilibrium. Economists know the role competitive markets have played in raising the average person’s standard of living. They also know that too much government intervention has the potential to reduce the ability of the market system to produce similar increases in living standards in the future.

But recall the difference between positive and normative analysis. Positive analysis is concerned with *what is*, and normative analysis is concerned with *what should be*. Our analysis of rent control and the federal farm programs in this chapter is positive analysis. We discussed the economic results of these programs. Whether these programs are desirable or undesirable is a normative question. Whether the gains to the winners more than make up for the losses to the losers and for the decline in economic efficiency is a matter of judgment and not strictly an economic question. Price ceilings and price floors continue to exist partly because people who understand their downside still believe they are good policies and therefore support them. The policies also persist because many people who support them do not understand the economic analysis in this chapter and so do not understand the drawbacks to these policies.

4.4 The Economic Effect of Taxes

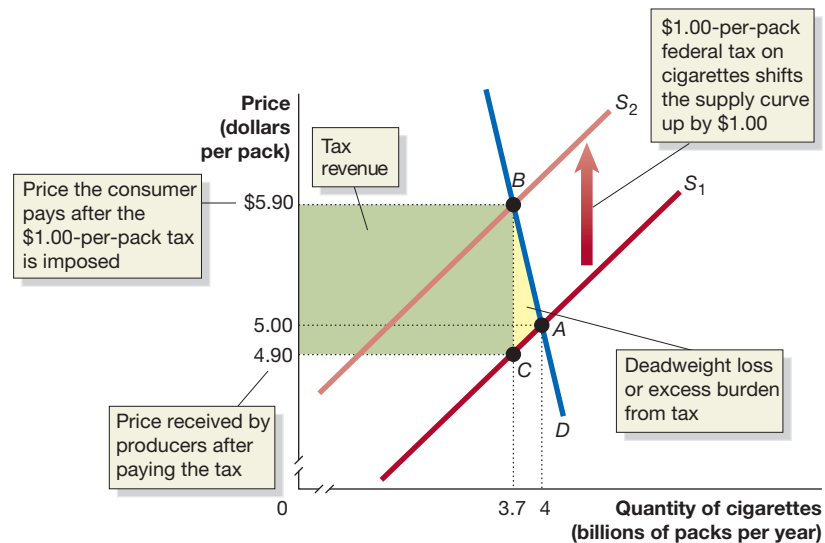

LEARNING OBJECTIVE: Analyze the economic effect of taxes.

Supreme Court Justice Oliver Wendell Holmes once remarked: “Taxes are what we pay for a civilized society.” When the government taxes a good or service, however, it affects the market equilibrium for that good or service. Just as with a price ceiling or price floor, one result of a tax is a decline in economic efficiency. Analyzing taxes is an important part of the field of economics known as *public finance*. In this section, we will use the model of demand and supply and the concepts of consumer surplus, producer surplus, and deadweight loss to analyze the economic effect of taxes.

The Effect of Taxes on Economic Efficiency

Whenever a government taxes a good or service, less of that good or service will be produced and consumed. For example, a tax on cigarettes will raise the cost of smoking and reduce the amount of smoking that takes place. We can use a demand and supply graph to illustrate this point. Figure 4.10 shows the market for cigarettes.

Without the tax, the equilibrium price of cigarettes would be \$5.00 per pack, and 4 billion packs of cigarettes would be sold per year (point A). If the federal government requires sellers of cigarettes to pay a \$1.00-per-pack tax, then their cost of selling cigarettes will increase by \$1.00 per pack. This increase in cost causes the supply curve for cigarettes to shift up by \$1.00 because sellers will now require a price that is \$1.00 greater to supply the same quantity of cigarettes. In Figure 4.10, the supply curve shifts up by \$1.00 to show the effect of the tax, and there is a new equilibrium price of \$5.90 and a new equilibrium quantity of 3.7 billion packs (point B).

MyEconLab Animation

Figure 4.10 The Effect of a Tax on the Market for Cigarettes

Without the tax, market equilibrium occurs at point A. The equilibrium price of cigarettes is \$5.00 per pack, and 4 billion packs of cigarettes are sold per year. A \$1.00-per-pack tax on cigarettes will cause the supply curve for cigarettes to shift up by \$1.00, from S_1 to S_2 . The new equilibrium occurs at point B. The price of cigarettes will increase by \$0.90, to \$5.90 per pack, and the quantity sold will fall to 3.7 billion packs. The tax on cigarettes has increased

the price paid by consumers from \$5.00 to \$5.90 per pack. Producers receive a price of \$5.90 per pack (point B), but after paying the \$1.00 tax, they are left with \$4.90 (point C). The government will receive tax revenue equal to the green-shaded box. Some consumer surplus and some producer surplus will become tax revenue for the government, and some will become deadweight loss, shown by the yellow-shaded area.

The federal government will collect tax revenue equal to the tax per pack multiplied by the number of packs sold, or \$3.7 billion. The area shaded in green in Figure 4.10 represents the government's tax revenue. Consumers will pay a higher price of \$5.90 per pack. Although sellers appear to be receiving a higher price per pack, once they have paid the tax, the price they receive falls from \$5.00 per pack to \$4.90 per pack. There is a loss of consumer surplus because consumers are paying a higher price. The price producers receive falls, so there is also a loss of producer surplus. Therefore, the tax on cigarettes has reduced *both* consumer surplus and producer surplus. Some of the reduction in consumer and producer surplus becomes tax revenue for the government. The rest of the reduction in consumer and producer surplus is equal to the deadweight loss from the tax, shown by the yellow-shaded triangle in the figure.

We can conclude that the true burden of a tax is not just the amount consumers and producers pay the government but also includes the deadweight loss. The deadweight loss from a tax is referred to as the *excess burden* of the tax. A tax is *efficient* if it imposes a small excess burden relative to the tax revenue it raises. One contribution economists make to government tax policy is to advise policymakers on which taxes are most efficient.

Tax Incidence: Who Actually Pays a Tax?

The answer to the question "Who pays a tax?" seems obvious: Whoever is legally required to send a tax payment to the government pays the tax. But there can be an important difference between who is legally required to pay the tax and who actually *bears the burden* of the tax. The actual division of the burden of a tax between buyers and sellers is referred to as **tax incidence**. For example, the federal government currently levies an excise tax of 18.4 cents per gallon of gasoline sold. Gas station owners collect this tax and forward it to the federal government, but who actually bears the burden of the tax?

Tax incidence The actual division of the burden of a tax between buyers and sellers in a market.

MyEconLab Animation

Figure 4.11

The Incidence of a Tax on Gasoline

With no tax on gasoline, the price would be \$2.50 per gallon, and 144 billion gallons of gasoline would be sold each year. A 10-cents-per-gallon excise tax shifts up the supply curve from S_1 to S_2 , raises the price consumers pay from \$2.50 to \$2.58, and lowers the price sellers receive from \$2.50 to \$2.48. Therefore, consumers pay 8 cents of the 10-cents-per-gallon tax on gasoline, and sellers pay 2 cents.

Determining Tax Incidence on a Demand and Supply Graph Suppose that currently the federal government does not impose a tax on gasoline. In Figure 4.11, equilibrium in the retail market for gasoline occurs at the intersection of the demand curve and supply curve, S_1 . The equilibrium price is \$2.50 per gallon, and the equilibrium quantity is 144 billion gallons per year. Now suppose that the federal government imposes a 10-cents-per-gallon tax. As a result of the tax, the supply curve for gasoline will shift up by 10 cents per gallon. At the new equilibrium, where the demand curve intersects the supply curve, S_2 , the price has risen by 8 cents per gallon, from \$2.50 to \$2.58. Notice that only in the extremely unlikely case that demand is a vertical line will the market price rise by the full amount of the tax. Consumers are paying 8 cents more per gallon. Sellers of gasoline receive a new higher price of \$2.58 per gallon, but after paying the 10-cents-per-gallon tax, they are left with \$2.48 per gallon, or 2 cents less than they were receiving in the old equilibrium.

Although the sellers of gasoline are responsible for collecting the tax and sending the tax receipts to the government, they do not bear most of the burden of the tax. In this case, consumers pay 8 cents of the tax because the market price has risen by 8 cents, and sellers pay 2 cents of the tax because after sending the tax to the government, they are receiving 2 cents less per gallon of gasoline sold. Expressed in percentage terms, consumers pay 80 percent of the tax, and sellers pay 20 percent of the tax.

Solved Problem 4.4

MyEconLab Interactive Animation

When Do Consumers Pay All of a Sales Tax Increase?

A student makes the following statement: “If the federal government raises the sales tax on gasoline by \$0.25, then the price of gasoline will rise by \$0.25. Consumers can’t get by without gasoline, so they have to pay the whole amount

of any increase in the sales tax.” Under what circumstances will the student’s statement be true? Use a graph of the market for gasoline to illustrate your answer.

Solving the Problem

Step 1: Review the chapter material. This problem is about tax incidence, so you may want to review the section “Tax Incidence: Who Actually Pays a Tax?” which begins on page 184.

Step 2: Draw a graph like Figure 4.11 to illustrate the circumstances when consumers will pay all of an increase in a sales tax.

Step 3: Use the graph to evaluate the statement. The graph shows that consumers will pay all of an increase in a sales tax only if the demand curve is a vertical line. It is very unlikely that the demand for gasoline would look like this because we expect that for every good, an increase in price will cause a decrease in the quantity demanded. Because the demand curve for gasoline is not a vertical line, the statement is incorrect.

MyEconLab Study Plan

Your Turn: For more practice, do related problem 4.8 on page 198 at the end of the chapter.

Does It Make a Difference Whether the Government Collects a Tax from Buyers or Sellers? We have already seen the important distinction between who is legally required to pay a tax and who actually bears the burden of a tax. We can reinforce this point by noting explicitly that the incidence of a tax does *not* depend on whether the government collects a tax from the buyers of a good or from the sellers. Figure 4.12 illustrates this point by showing the effect on equilibrium in the market for gasoline if a 10-cents-per-gallon tax is imposed on buyers rather than on sellers. That is, we are now assuming that instead of sellers having to collect the 10-cents-per-gallon tax at the pump, buyers are responsible for keeping track of how many gallons of gasoline they purchase and sending the tax to the government. (Of course, it would be very difficult for buyers to keep track of their purchases or for the government to check whether they were paying all of the taxes they owe. That is why the government collects the tax on gasoline from sellers.)

Figure 4.12 is similar to Figure 4.11 except that it shows the gasoline tax being imposed on buyers rather than on sellers. In Figure 4.12, the supply curve does not shift because nothing has happened to change the quantity of gasoline sellers are willing to supply at any given price. The demand curve has shifted, however, because consumers now have to pay a 10-cent tax on every gallon of gasoline they buy. Therefore, at every quantity, they are willing to pay a price 10 cents lower than they would have without the tax. In the figure, we indicate the effect of the tax by shifting the demand curve down by 10 cents, from D_1 to D_2 . Once the tax has been imposed and the demand curve has shifted down, the new equilibrium quantity of gasoline is 140 billion gallons, which is exactly the same as in Figure 4.11.

MyEconLab Animation

Figure 4.12 The Incidence of a Tax on Gasoline Paid by Buyers

With no tax on gasoline, the demand curve is D_1 . If a 10-cents-per-gallon tax is imposed that consumers are responsible for paying, the demand curve shifts down by the amount of the tax, from D_1 to D_2 .

In the new equilibrium, consumers pay a price of \$2.58 per gallon, including the tax. Producers receive \$2.48 per gallon. The result is the same as when producers were responsible for paying the tax.

The new equilibrium price after the tax is imposed appears to be different in Figure 4.12 than in Figure 4.11, but if we include the tax, buyers will pay the same price and sellers will receive the same price in both figures. To see this point, notice that in Figure 4.11, buyers pay sellers a price of \$2.58 per gallon. In Figure 4.12, they pay sellers only \$2.48, but they must also pay the government a tax of 10 cents per gallon. So, the total price buyers pay remains \$2.58 per gallon. In Figure 4.11, sellers receive \$2.58 per gallon from buyers, but after they pay the tax of 10 cents per gallon, they are left with \$2.48, which is the same amount they receive in Figure 4.12.

Is the Burden of the Social Security Tax Really Shared Equally between Workers and Firms?

Most people who receive paychecks have several different taxes withheld by their employers, who forward the taxes directly to the government. In fact, after getting their first job, many people are shocked when they discover the gap between their gross pay and their net pay after taxes have been deducted. The largest tax many people of low or moderate income pay is FICA, which stands for the Federal Insurance Contributions Act. FICA funds the Social Security and Medicare programs, which provide income and health care to the elderly and disabled. FICA is sometimes referred to as the *payroll tax*. When Congress passed the act, it wanted employers and workers to equally share the burden of the tax. Currently, FICA is 15.3 percent of wages, with workers paying 7.65 percent, which is withheld from their paychecks, and employers paying the other 7.65 percent.

But does requiring workers and employers to each pay half the tax mean that the burden of the tax is also shared equally? Our discussion in this chapter shows that the answer is “no.” In the labor market, employers are buyers, and workers are sellers. As we saw in the example of the federal tax on gasoline, whether the tax is collected from buyers or from sellers does not affect the incidence of the tax. Most economists believe,

in fact, that the burden of FICA falls almost entirely on workers. The following figure, which shows the market for labor, illustrates why.

In the market for labor, the demand curve represents the quantity of labor demanded by employers at various wages, and the supply curve represents the quantity of labor supplied by workers at various wages. The intersection of the demand curve and the supply curve determines the equilibrium wage. In both panels, the equilibrium wage without a Social Security payroll tax is \$10 per hour. For simplicity, let's assume that the payroll tax equals \$1 per hour of work. In panel (a), we assume that employers must pay the tax. The tax causes the demand for labor curve to shift down by \$1 at every quantity of labor because firms must now pay a \$1 tax for every hour of labor they hire. We have drawn the supply curve for labor as being very steep because most economists believe the quantity of labor supplied by workers does not change much as the wage rate changes. In panel (a), after the tax is imposed, the equilibrium wage declines from \$10 per hour to \$9.05 per hour. Firms are now paying a total of \$10.05 for every hour of work they hire: \$9.05 in wages to workers and \$1 in tax to the government. In other words, workers have paid \$0.95 of the \$1 tax, and firms have paid only \$0.05.

Panel (b) shows that this result is exactly the same when the tax is imposed on workers rather than on firms. In this case, the tax causes the supply curve for labor to shift up by \$1 at every quantity of labor because workers must now pay a tax of \$1 for every hour they work. After the tax is imposed, the equilibrium wage increases to \$10.05 per hour. But workers receive only \$9.05 after they have paid the \$1.00 tax. Once again, workers have paid \$0.95 of the \$1 tax, and firms have paid only \$0.05.

Although the figure presents a simplified analysis, it reflects the conclusion of most economists who have studied the incidence of FICA: Even though Congress requires employers to pay half the tax and workers to pay the other half, in fact, the burden of the tax falls almost entirely on workers. This conclusion would not be changed even if Congress revised the law to require either employers or workers to pay all of the tax. The forces of demand and supply working in the labor market, and not Congress, determine the incidence of the tax.

Does Rent Control Make It Easier for You to Find an Affordable Apartment?

At the beginning of the chapter, we posed the following question: If you have job offers in two different cities, one with rent control and one without, are you more likely to find an affordable apartment in the city with rent control, or would you be better off looking for an apartment in a city without rent control? This chapter has shown that although rent control can keep rents lower than they might otherwise be, it can also lead to a permanent shortage of apartments. You may have to search for a long time to find a suitable apartment, and landlords may even ask you to give them additional payments in violation of the rent control law, which would make your actual rent higher than the controlled rent. Finding an apartment in a city without rent control should be much easier, although the rent may be higher.

Conclusion

Our discussion of the model of demand and supply shows that markets free from government intervention eliminate surpluses and shortages and do a good job of responding to the wants of consumers. We have seen that both consumers and firms sometimes try to use the government to change market outcomes in their favor. The concepts of consumer surplus, producer surplus, and deadweight loss allow us to measure the benefits consumers and producers receive from competitive market equilibrium. These concepts also allow us to measure the effects of government price floors and price ceilings and the economic effect of taxes.

MALIBU TIMES

Airbnb to Begin Collecting Taxes for City: Nearly a Year after Subpoenas Were Sent, Airbnb and Malibu Have Come to an Agreement

Those who rent out their homes or guest houses during busy weekends or keep a rental property by the beach to make extra cash will soon be kicking a few bucks back to Malibu [California] since Airbnb, one of the last holdouts against Malibu's demand for taxes, has finally come to an agreement with the City.

a City Council's May 2014 decision to subpoena vacation rental sites for info so they could collect transient occupancy "hotel" tax (TOT) from individuals leasing out private homes raised a few eyebrows around town, but nearly a year later, Airbnb has finally responded and, beginning on April 20, four out of the five sites they requested will now be handing the City its 12%.

"We are pleased to add Malibu to the growing list of cities where Airbnb is able to collect and remit occupancy taxes on behalf of our hosts, and where local rules embrace home sharing and the peer to peer economy," reads the official Airbnb announcement, authored by regional head of public policy David Owen.

City Attorney Christi Hogin explained that Airbnb is essentially agreeing to provide a service to those

who rent out houses and apartments on its site, who are the ones legally responsible for collecting the tax.

"Airbnb is going to make it easy on the hosts by collecting the tax on their behalf and remitting it to the City, which the City is thrilled with," Hogin said.

"We think that Airbnb is totally doing the right thing here," Hogin added.

b The story began 11 months ago, when Assistant City Manager Reva Feldman prepared a staff report for City Council suggesting they go after rental sites, including Airbnb, HomeAway (owners of VRBO and FlipKey) and YBYC.

According to Feldman, the City was missing out on hundreds of thousands of dollars in tax revenue.

Now, Feldman says, though numbers from Airbnb aren't finalized, the city expects a bump from TOT.

"I can tell you that we expect for this fiscal year to get \$450,000," Feldman said, "That's what we expect [now]. But I don't know until Airbnb provides me with data, what we can expect."

Hogin added that the tax money goes back to renters and hosts. "The money that we can use from those taxes is basically used for police, fire, roads, clean water: all of those things that both the residents and visitors employ," Hogin said.

As for the other sites issued subpoenas, only HomeAway is holding out. According to Feldman, there doesn't seem to be much hope for the City to

collect the TOT from them, since they are not under legal obligation.

Since HomeAway does not have an L.A. County office, the subpoena from the City does not put any pressure on them, and, in addition, unlike some of the other sites, VRBO and FlipKey do not collect rental fees themselves.

"They're just an advertising site; they don't collect revenue through the site," Feldman said. "Unless they willingly comply, there's nothing we can do further with that."

c The City is making its money, but there has been little word about whether the tax will help cut down on vacation rentals, which was listed as a primary reason to issue the subpoenas in spring 2014.

"This is not a revenue-generating item. The reason we're doing this, the genesis of this, was we've been getting a tremendous amount of complaints from residents throughout all areas of the city," said Councilman Lou La Monte during a May 2014 council meeting.

Airbnb seems to have taken its agreement with the City to mean it's more welcome than ever to operate in Malibu neighborhoods.

"Our community in Malibu already brings significant economic and cultural benefits to the city, and this is another way we can make it even stronger," reads the Airbnb statement.

Source: Emily Sawicki, "Airbnb to Begin Collecting Taxes for City: Nearly a Year after Subpoenas Were Sent, Airbnb and Malibu Have Come to an Agreement," *Malibu Times*, April 8, 2015.

Key Points in the Article

The affluent beach community of Malibu, California, has reached an agreement with Airbnb that will require the company to collect hotel taxes on behalf of its customers who rent their homes through the Internet site. Beginning in April 2015, the city's 12 percent transient occupancy tax (TOT) will apply to anyone leasing out private homes via Airbnb. The city's initial estimate of first-year tax revenues collected from Airbnb was \$450,000, which City Attorney David Hogin said will go toward services such as police and fire protection. While the collection of the TOT will generate revenue for the city, the primary motivation for collecting the tax was to cut down on vacation rentals in the community.

Analyzing the News

a Airbnb is an Internet site that matches homeowners who want to rent out rooms or their entire homes for a short period with travelers looking for short-term rentals. Since the company's inception in 2008, Airbnb has been criticized by hotel companies and some local government officials for not collecting local hotel taxes from its customers. Over the past few years, Airbnb has made an effort to appease the cities and hotel companies by agreeing to collect these taxes, as was demonstrated by the company's agreement with the city of Malibu to collect the 12 percent TOT. The figure below shows a

hypothetical example of the effect of this tax on the market for vacation rental homes in Malibu. Without the tax, the equilibrium rent is \$1,000 per week, with a quantity of 400 homes being rented each month. With a 12 percent tax (\$120), the supply curve shifts up by \$120, increasing the price the consumer pays to \$1,060, decreasing the price the homeowner receives to \$940, and decreasing the quantity of homes being rented to 320. The tax revenue is equal to \$38,400 per month (\$120 per rental \times 320 rentals).

b The imposition of the 12 percent tax on Airbnb rentals will generate revenue for the city of Malibu, but it will also affect economic efficiency by reducing consumer and producer surplus. The renters (consumers), will pay a higher price for their vacation home rentals, which reduces consumer surplus, and the homeowners, or suppliers, will receive a lower price for renting their homes, which reduces producer surplus. Some of the reduction in consumer and producer surplus will become tax revenue for the city of Malibu, which the assistant city manager estimates at \$450,000 for the first fiscal year the tax is in effect, but the rest of the loss in consumer and producer surplus is deadweight loss from the tax, a result of the decrease in the number of rentals due to the imposition of the tax.

c Although the imposition of a tax does generate revenue for Malibu, additional revenue is not necessarily the reason

certain taxes are imposed. While the city pledged that the tax will be used to help pay for city services, the primary motivation for this tax is to discourage vacation home rentals. The city council cited complaints from residents about the number of homes in the community being used as short-term rental properties and proposed charging this tax as a way to reduce the number of rentals. As the figure below illustrates, when a tax is imposed, supply decreases, as does the equilibrium quantity of the product or service.

Thinking Critically about Policy

1. The figure below shows the market for vacation rental homes before and after the imposition of a 12 percent tax. How can we use the figure to measure the effect the tax has on economic efficiency? Redraw the graph and show the area representing the excess burden created by the implementation of the tax.
2. Airbnb has begun collecting hotel taxes in a number of cities. The figure below shows a hypothetical example of the effects of this tax on the market for vacation rental homes in Malibu. Redraw the graph to show what happens if renters, instead of Airbnb, were responsible for directly paying the tax to the city. Explain any differences in price, quantity, and tax incidence.

The market for vacation rental homes before and after the imposition of a 12 percent hotel tax shows that the tax shifts the supply curve up by \$120, increasing the price paid by the consumer from \$1,000 to \$1,060 and decreasing the price received by the homeowner from \$1,000 to \$940.

Consumer Surplus and Producer Surplus, pages 168–172

LEARNING OBJECTIVE: Distinguish between the concepts of consumer surplus and producer surplus.

Summary

Although most prices are determined by demand and supply in markets, the government sometimes imposes *price ceilings* and *price floors*. A **price ceiling** is a legally determined maximum price that sellers may charge. A **price floor** is a legally determined minimum price that sellers may receive. Economists analyze the effects of price ceilings and price floors by using the concepts of *consumer surplus*, *producer surplus*, and *deadweight loss*. **Marginal benefit** is the additional benefit to a consumer from consuming one more unit of a good or service. The demand curve is also a marginal benefit curve. **Consumer surplus** is the difference between the highest price a consumer is willing to pay for a good or service and the actual price the consumer pays. The total amount of consumer surplus in a market is equal to the area below the demand curve and above the market price. **Marginal cost** is the additional cost to a firm of producing one more unit of a good or service. The supply curve is also a marginal cost curve. **Producer surplus** is the difference between the lowest price a firm is willing to accept for a good or service and the price it actually receives. The total amount of producer surplus in a market is equal to the area above the supply curve and below the market price.

for their rides with their smartphone apps. Uber's prices fluctuate with the demand for the service. This "surge pricing" can result in different prices for the same distance traveled at different times of day or days of the week. Annie Lowrey, a writer for the *New York Times*, explained that she paid \$13 for a 10 P.M. two-mile trip in downtown Washington, DC, on New Year's Eve. Three hours later she paid \$47 for the return trip to her home. Did she receive negative consumer surplus on her return trip? Briefly explain.

Review Questions

- 1.1 What is marginal benefit? Why is the demand curve referred to as a marginal benefit curve?
- 1.2 What is marginal cost? Why is the supply curve referred to as a marginal cost curve?
- 1.3 Define consumer surplus and draw a graph to show the area representing consumer surplus.
- 1.4 Define producer surplus. Draw a graph to show the area that represents producer surplus.

Problems and Applications

- 1.5 Suppose Wolfram has been looking for a vintage Fender Telecaster for years, but has never found one in good condition. He is prepared to pay a considerable amount for it; one day he finds one at a street market in Berlin at a bargain of €1,000. What is Wolfram's consumer surplus?

- 1.10** A student makes the following argument: “When a market is in equilibrium, there is no consumer surplus. We know this because in equilibrium, the market price is equal to the price consumers are willing to pay for the good.” Briefly explain whether you agree with the student’s argument.
- 1.11** In the following graph, is the consumer surplus larger with demand curve D_1 or demand curve D_2 ? Briefly explain. Compare the producer surplus with demand curve D_1 and with demand curve D_2 .

- 1.12** Assume that the following graph illustrates the market for a breast cancer–fighting drug, without which breast cancer patients cannot survive. What is the consumer

surplus in this market? How does it differ from the consumer surplus in the markets you have studied up to this point?

- 1.13** (Related to the **Making the Connection** on page 170) The *Making the Connection* states that the value of the area representing consumer surplus from broadband Internet service is \$890.4 million. Use the information from the graph in the *Making the Connection* to show how this value was calculated. (For a review of how to calculate the area of a triangle, see the appendix to Chapter 1.)
- 1.14** Consider a situation where consumers are allowed to participate in auctions as bidders in order to determine prices, rather than paying fixed prices for different goods and services. Would this lead to an increase or a decrease in consumer surplus? How would the producer surplus be affected in this case?

4.2

The Efficiency of Competitive Markets, pages 173–175

LEARNING OBJECTIVE: Explain the concept of economic efficiency.

Summary

Equilibrium in a competitive market is economically efficient. **Economic surplus** is the sum of consumer surplus and producer surplus. **Economic efficiency** is a market outcome in which the marginal benefit to consumers from the last unit produced is equal to the marginal cost of production and in which the sum of consumer surplus and producer surplus is at a maximum. When the market price is above or below the equilibrium price, there is a reduction in economic surplus. The reduction in economic surplus resulting from a market not being in competitive equilibrium is called the **deadweight loss**.

Review Questions

- Define *economic surplus* and *deadweight loss*.
- Why is equilibrium in a competitive market considered to be efficient?

Problems and Applications

- In 2012, an unexpected and persistent drought affected crop production across Europe, including the United Kingdom. The most widely grown crop in the United Kingdom is wheat. Use a demand and supply graph of the wheat market to illustrate what happens to the consumer surplus and producer surplus as a result of the drought.

- 2.4 Briefly explain whether you agree with the following statement: “A lower price in a market always increases economic efficiency in that market.”
- 2.5 Do deadweight losses occur in a competitive market which is in equilibrium? Briefly explain your reasoning.
- 2.6 According to a news article in *The Telegraph*, McDonald’s has decided to introduce a 100 percent organic-beef burger in Germany. Using 100 percent organic beef increases their cost. Suppose consumers react to the news of McDonald’s selling 100 percent organic-beef burgers by increasing their demand for them. Can you tell whether economic surplus will increase in the market for burgers? Use a graph of the market for burgers to illustrate your answer.
- Source:** Camilla Turner, “McDonald’s to Trial 100 Per cent Organic Burger in Germany,” *The Telegraph*, September 26, 2015.
- 2.7 If a market is in equilibrium would it be desirable to move to a different market outcome with a lower economic surplus but a higher consumer surplus? Briefly explain.
- 2.8 Using the following graph, show the effects on consumer surplus and producer surplus of an increase in supply from S_1 to S_2 . By how much does economic surplus increase?

- 2.9 A student argues: “Economic surplus is greatest at the level of output where the difference between marginal benefit and marginal cost is largest.” Do you agree? Briefly explain.
- 2.10 Using the following graph, explain why economic surplus would be smaller if Q_1 or Q_3 were the quantity produced than if Q_2 is the quantity produced.

4.3 Government Intervention in the Market: Price Floors and Price Ceilings, pages 175–183

LEARNING OBJECTIVE: Explain the economic effect of government-imposed price floors and price ceilings.

Summary

Producers or consumers who are dissatisfied with the equilibrium in a market can attempt to convince the government to impose a price floor or a price ceiling. Price floors usually increase producer surplus, decrease consumer surplus, and cause a deadweight loss. Price ceilings usually increase consumer surplus, reduce producer surplus, and cause a deadweight loss. The results of the government imposing price ceilings and price floors are that some people win, some people lose, and a loss of economic

efficiency occurs. Price ceilings and price floors can lead to a **black market**, in which buying and selling take place at prices that violate government price regulations. Positive analysis is concerned with *what is*, and normative analysis is concerned with *what should be*. Positive analysis shows that price ceilings and price floors cause deadweight losses. Whether these policies are desirable or undesirable, though, is a normative question.

Review Questions

- 3.1 Briefly explain the following statement: “All individuals are satisfied by the competitive market equilibrium outcome because it is efficient. Therefore, there is no need for government intervention.”
- 3.2 Provide an example of a price ceiling. Why should governments enforce price ceilings?
- 3.3 Why are black markets crucial for the success of government policies like price floors and price ceilings?
- 3.4 Can economic analysis provide a final answer to the question of whether the government should intervene in markets by imposing price ceilings and price floors? Briefly explain.

Problems and Applications

- 3.5 The following graph shows the market for apples. Assume

that the government has imposed a price floor of \$10 per crate.

- a. How many crates of apples will be sold to consumers after the price floor has been imposed?
 - b. Will there be a shortage or a surplus of apples? If there is a shortage or a surplus, how large will it be?
 - c. Will apple producers benefit from the price floor? If so, explain how they will benefit.
- 3.6 Use the information on the kumquat market in the table to answer the following questions:

Price (per Crate)	Quantity Demanded (Millions of Crates per Year)	Quantity Supplied (Millions of Crates per Year)
\$10	120	20
15	110	60
20	100	100
25	90	140
30	80	180
35	70	220

- a. What are the equilibrium price and quantity? How much revenue do kumquat producers receive when the market is in equilibrium? Draw a graph showing the market equilibrium and the area representing the revenue kumquat producers receive.
- b. Suppose the federal government decides to impose a price floor of \$30 per crate. Now how many crates of kumquats will consumers purchase? How much revenue will kumquat producers receive? Assume that the government does not purchase any surplus kumquats. On your graph from part (a), show the price floor, the change in the quantity of kumquats purchased, and the revenue kumquat producers receive after the price floor is imposed.

- c. Suppose the government imposes a price floor of \$30 per crate and purchases any surplus kumquats from producers. Now how much revenue will kumquat producers receive? How much will the government spend on purchasing surplus kumquats? On your graph from part (a), show the area representing the amount the government spends to purchase the surplus kumquats.

- 3.7 Suppose that the government sets a price floor for milk that is above the competitive equilibrium price and that the government does not purchase any surplus milk.

- a. Draw a graph showing this situation. Be sure your graph shows the competitive equilibrium price, the price floor, the quantity that would be sold in competitive equilibrium, and the quantity that would be sold with the price floor.
- b. Compare the economic surplus in this market when there is a price floor and when there is not.

- 3.8 According to a *BBC* article, in 2013, the Indian government imposed a price ceiling of 6.56 INR on contraception. Prior to the government intervention the average price was 25 INR.

- a. Draw a graph showing the effect of the price ceiling on the market for certain contraceptive devices. Be sure that your graph shows:
 - i. The price and quantity of certain contraceptive devices before and after the price ceiling is imposed
 - ii. The areas representing consumer surplus and producer surplus before and after the price ceiling is imposed
 - iii. The area of deadweight loss
- b. Will consumers purchasing the product definitely be made better off by the price ceiling? Briefly explain.

- 3.9 According to a *New York Times* article, the Venezuelan government “imposes strict price controls that are intended to make a range of foods and other goods more affordable for the poor. They are often the very products that are the hardest to find.”

- a. Why would imposing price controls on goods make them hard to find?
- b. One of the goods subject to price controls was toothpaste. Draw a graph to illustrate this situation. On your graph, be sure to indicate the areas representing consumer surplus, producer surplus, and deadweight loss.

George Osborne, the United Kingdom's Chancellor of the Exchequer, is considering to increase the minimum wage in the United Kingdom (currently at £6.70). While an increase in minimum wage will have the effect to raise some people out of poverty, the plan has been criticized by the Low Pay Commission based on the figure that more than 60,000 jobs may be lost because of the increase in minimum wage. Why might raising the minimum wage reduce employment? How would it raise some people out of poverty? What effect might these estimates have on a normative analysis of the minimum wage?

3.11 (Related to the Chapter Opener on page 167) If London were to introduce a rent control law, would the prices for short-term rentals in the city listed on peer-to-peer sites be likely to rise or fall? Briefly explain.

3.12 (Related to the Chapter Opener on page 167) The competitive equilibrium rent for a 1-bedroom apartment in the city of Milan is currently €670 per month. Suppose that the city council decides to enact rent control and establish a price ceiling of €500 per month for 1-bedroom apartments. Briefly explain whether rent control is likely to make each of the following people better or worse off:

- Someone currently renting a 1-bedroom apartment in Milan
- Someone who will be moving to Milan next year and who intends to rent a 1 bedroom apartment
- A landlord who intends to abide by the rent control law
- A landlord who intends to ignore the law and illegally charge the highest rent possible for his apartments

3.13 (Related to the Don't Let This Happen to You on page 179) Briefly explain whether you agree with the following statement: "If there is a shortage of a good, it must be scarce, but there is not a shortage of every scarce good."

3.14 (Related to Solved Problem 4.3 on page 180) Use the information on the market for apartments in Bay City in the table to answer the following questions:

Rent	Quantity Demanded	Quantity Supplied
\$500	375,000	225,000
600	350,000	250,000
700	325,000	275,000
800	300,000	300,000
900	275,000	325,000
1,000	250,000	350,000

- In the absence of rent control, what is the equilibrium rent, and what is the equilibrium quantity of apartments rented? Draw a demand and supply graph of the market for apartments to illustrate your answer. In equilibrium, will there be any renters who are unable to find an apartment to rent or any landlords who are unable to find a renter for an apartment?
- Suppose the government sets a ceiling of \$600 per month on rents. What is the quantity of apartments demanded, and what is the quantity of apartments supplied?

- Assume that all landlords abide by the law in part (b). Use a demand and supply graph to illustrate the effect of this price ceiling on the market for apartments. Be sure to indicate on your graph each of the following: (i) the area representing consumer surplus after the price ceiling has been imposed, (ii) the area representing producer surplus after the price ceiling has been imposed, and (iii) the area representing the dead-weight loss after the price ceiling has been imposed.
- Assume that the quantity of apartments supplied is the same as you determined in (b), but now assume that landlords ignore the law and rent this quantity of apartments for the highest rent they can get. Briefly explain what this rent will be.

3.15 (Related to the Making the Connection on page 182)

According to a news story, after taxi drivers in Paris protested against Uber, the government passed a new regulation "requiring a minimum 15-minute wait between the time a car is booked and the passenger is picked up." Why would taxi drivers believe they benefit from such a regulation? Would the regulation be likely to increase or decrease economic efficiency in the market for hired rides? Briefly explain.

3.16 A student makes the following argument: "A price floor reduces the amount of a product that consumers buy because it keeps the price above the competitive market equilibrium. A price ceiling, though, increases the amount of a product that consumers buy because it keeps the price below the competitive market equilibrium." Do you agree with the student's reasoning? Use a demand and supply graph to illustrate your answer.

3.17 University towns with major football programs experience an increase in demand for hotel rooms during home football weekends. Hotels respond to the increase in demand by increasing the prices they charge for rooms. Periodically, there is an outcry against the higher prices and accusations of "price gouging."

- Draw a demand and supply graph of the market for hotel rooms in Boostertown for weekends with home football games and another graph for weekends without home football games. If the Boostertown city council passes a law stating that prices for rooms are not allowed to rise, what would happen to the market for hotel rooms during home football game weekends? Show your answer on your graph.
- If the prices of hotel rooms are not allowed to increase, what will be the effect on out-of-town football fans?
- How might the city council's law affect the supply of hotel rooms over time? Briefly explain.
- University towns are not the only places that face peak and nonpeak "seasons." Can you think of other locations that face a large increase in demand for hotel rooms during particular times of the year? Why do we typically not see laws limiting the prices hotels can charge during peak seasons?

3.18 Suppose that initially the gasoline market is in equilibrium, at a price of \$2.50 per gallon and a quantity of 45 million gallons per month. Then a war in the Middle East disrupts imports of oil into the United States, shifting the supply curve for gasoline from S_1 to S_2 . The price of

gasoline begins to rise, and consumers protest. The federal government responds by setting a price ceiling of \$2.50 per gallon. Use the graph to answer the following questions.

- If there were no price ceiling, what would be the equilibrium price of gasoline, the quantity of gasoline demanded, and the quantity of gasoline supplied? Now assume that the price ceiling is imposed and that there is no black market in gasoline. What are the price of gasoline, the quantity of gasoline demanded, and the quantity of gasoline supplied? How large is the shortage of gasoline?
- Assume that the price ceiling is imposed, and there is no black market in gasoline. Show on the graph the areas representing consumer surplus, producer surplus, and deadweight loss.

- Now assume that there is a black market, and the price of gasoline rises to the maximum that consumers are willing to pay for the amount supplied by producers, at \$2.50 per gallon. Show on the graph the areas representing producer surplus, consumer surplus, and deadweight loss.
- Are consumers made better off with the price ceiling than without it? Briefly explain.

3.19 An editorial in the *Economist* magazine discusses the fact that in most countries—including the United States—it is illegal for individuals to buy or sell body parts, such as kidneys.

- Draw a demand and supply graph for the market for kidneys. Show on your graph the legal maximum price of zero and indicate the quantity of kidneys supplied at this price. (*Hint:* Because we know that some kidneys are donated, the quantity supplied will not be zero.)
- The editorial argues that buying and selling kidneys should be legalized:

With proper regulation, a kidney market would be a big improvement over the current sorry state of affairs. Sellers could be checked for disease and drug use, and cared for after operations. . . . Buyers would get better kidneys, faster. Both sellers and buyers would do better than in the illegal market, where much of the money goes to middlemen.

Do you agree with this argument? Should the government treat kidneys like other goods and allow the market to determine the price?

The Economic Effect of Taxes, pages 183–188

LEARNING OBJECTIVE: Analyze the economic effect of taxes.

Summary

Most taxes result in a loss of consumer surplus, a loss of producer surplus, and a deadweight loss. The true burden of a tax is not just the amount consumers and producers pay to the government but also includes the deadweight loss. The deadweight loss from a tax is called the excess burden of the tax. **Tax incidence** is the actual division of the burden of a tax. In most cases, consumers and firms share the burden of a tax levied on a good or service.

MyEconLab Visit www.myeconlab.com to complete select exercises online and get instant feedback.

Review Questions

- What is meant by *tax incidence*?
- Differentiate between people who are legally taxable and those who actually bear the burden.
- The autonomous Spanish community of Catalonia levies a tourist tax. Tourists incur the tax while paying for accommodation, and the local government collects this tax from the hotel owners. Would it make a difference to

the local government if it collected the tax directly from the tourists?

- As explained in the chapter, economic efficiency is a market outcome in which the marginal benefit to consumers of the last unit produced is equal to its marginal cost of production. Using this explanation of economic efficiency, explain why a tax creates a deadweight loss.

Problems and Applications

- Suppose the current equilibrium price of a quarter-pound hamburger is \$5, and 10 million quarter-pound hamburgers are sold per month. After the federal government imposes a tax of \$0.50 per hamburger, the equilibrium price of hamburgers rises to \$5.20, and the equilibrium quantity falls to 9 million. Illustrate this situation with a demand and supply graph. Be sure your graph shows the equilibrium price before and after the tax; the equilibrium quantity before and after the tax; and the areas representing consumer surplus after the tax, producer surplus after the tax, tax revenue collected by the government, and deadweight loss.

4.6 The following graph shows the effect of a tax imposed on soft drinks. Use this graph to answer the questions.

- Which areas in the graph represent the excess burden (deadweight loss) of the tax?
 - Which areas represent the revenues collected by the government from the tax?
 - Would this tax on soft drinks be considered efficient? Briefly explain.
- 4.7 Use the following graph of the market for cigarettes to answer the questions.

- According to the graph, how much is the government tax on cigarettes?
- What price do producers receive after paying the tax?
- How much tax revenue does the government collect?
- How would the graph be different if the tax were collected from the buyers of cigarettes?
- If the tax were collected from buyers, what would be the new equilibrium price that buyers pay producers of cigarettes?
- Including the tax, what would be the total amount that cigarette buyers pay per pack?

4.8 (Related to Solved Problem 4.4 on page 185) Suppose the Italian government decides to impose a sales tax of €1.00 per pizza. Briefly explain whether you agree with the following statement made by a representative of the pizza industry:

The pizza industry is very competitive. As a result, pizza sellers will have to pay the whole tax because they are unable to pass any of it on to consumers in the form of higher prices. Therefore, a sales tax of €1.00 per pizza will result in pizza sellers receiving €1.00 less on each pizza sold, after paying the tax.

Illustrate your answer with a graph.

4.9 (Related to the Making the Connection on page 187) According to a news story, Mexico's soda tax has resulted in a reduction in the sales of sugary drinks by 6 percent. For each bottle of soda drink, the government collects tax from the seller. Briefly explain the effect that the process of soda tax collection in Mexico has on the price of a bottle of sugary drink purchased by a consumer in a supermarket.

4.10 (Related to the Making the Connection on page 187) Suppose the government imposes a payroll tax of \$1 per hour of work and collects the tax from employers. Use a graph for the market for labor to show the effect of the payroll tax, assuming the special case of a vertical supply curve of labor. By how much does the new equilibrium wage that employers pay workers fall?

Quantitative Demand and Supply Analysis

LEARNING OBJECTIVE: Use quantitative demand and supply analysis.

Graphs help us understand economic change *qualitatively*. For instance, a demand and supply graph can tell us that if household incomes rise, the demand curve for a normal good will shift to the right, and the price of the good will rise. Often, though, economists, business managers, and policymakers want to know more than the qualitative direction of change; they want a *quantitative estimate* of the size of the change.

In this chapter, we carried out a qualitative analysis of rent controls. We saw that imposing rent controls involves a trade-off: Renters as a group gain, but landlords lose, and the market for apartments becomes less efficient, as shown by the deadweight loss. To better evaluate rent controls, we need to know more than just that these gains and losses exist; we need to know how large they are. A quantitative analysis of rent controls will tell us how large the gains and losses are.

Demand and Supply Equations

The first step in a quantitative analysis is to supplement our use of demand and supply curves with demand and supply *equations*. Economists use data on prices, quantities, and other economic variables to statistically estimate equations for demand and supply curves. For example, suppose that economists have estimated that the demand for apartments in New York City is:

$$Q^D = 4,750,000 - 1,000P,$$

and the supply of apartments is:

$$Q^S = -1,000,000 + 1,300P.$$

We have used Q^D for the quantity of apartments demanded per month, Q^S for the quantity of apartments supplied per month, and P for the apartment rent, in dollars per month. In reality, both the quantity of apartments demanded and the quantity of apartments supplied will depend on more than just the rental price of apartments in New York City. The demand for apartments in New York City will also depend, for instance, on the average incomes of families in the New York area and on the rents of apartments in the surrounding cities. For simplicity, we will ignore these other factors.

With no government intervention, we know that at competitive market equilibrium, the quantity demanded must equal the quantity supplied, or:

$$Q^D = Q^S.$$

We can use this equation, which is called an *equilibrium condition*, to solve for the equilibrium monthly apartment rent by setting the quantity demanded from the demand equation equal to the quantity supplied from the supply equation:

$$4,750,000 - 1,000P = -1,000,000 + 1,300P$$

$$5,750,000 = 2,300P$$

$$P = \frac{5,750,000}{2,300} = \$2,500.$$

We can then substitute this price back into either the supply equation or the demand equation to find the equilibrium quantity of apartments rented:

$$Q^D = 4,750,000 - 1,000P = 4,750,000 - 1,000(2,500) = 2,250,000,$$

or:

$$Q^S = -1,000,000 + 1,300P = -1,000,000 + 1,300(2,500) = 2,250,000.$$

Figure 4A.1 illustrates the information from these equations in a graph. The figure shows the values for rent when both the quantity supplied and the quantity demanded are zero. These values can be calculated from the demand and supply equations by setting Q^D and Q^S equal to zero and solving for price:

$$Q^D = 0 = 4,750,000 - 1,000P$$

$$P = \frac{4,750,000}{1,000} = \$4,750$$

and:

$$Q^S = 0 = -1,000,000 + 1,300P$$

$$P = \frac{-1,000,000}{-1,300} = \$769.23.$$

Calculating Consumer Surplus and Producer Surplus

Figure 4A.1 shows consumer surplus and producer surplus in this market.

Recall that the sum of consumer surplus and producer surplus equals the net benefit that renters and landlords receive from participating in the market for apartments. We can use the values from the demand and supply equations to calculate the value of consumer surplus and producer surplus. Remember that consumer surplus is the area below the demand curve and above the line representing market price. Notice that this area forms a right triangle because the demand curve is a straight line—it is *linear*. As we noted in the appendix to Chapter 1, the area of a triangle is equal to $\frac{1}{2} \times \text{Base} \times \text{Height}$. In this case, the area is:

$$\frac{1}{2} \times (2,250,000) \times (4,750 - 2,500) = \$2,531,250,000.$$

So, this calculation tells us that the consumer surplus in the market for rental apartments in New York City is about \$2.5 billion per month.

Figure 4A.1

Graphing Supply and Demand Equations

After statistically estimating supply and demand equations, we can use the equations to draw supply and demand curves. In this case, the equilibrium rent for apartments is \$2,500 per month, and the equilibrium quantity of apartments rented is 2,250,000. The supply equation tells us that at a rent of \$769, the quantity of apartments supplied will be zero. The demand equation tells us that at a rent of \$4,750, the quantity of apartments demanded will be zero. The areas representing consumer surplus and producer surplus are also indicated on the graph.

MyEconLab Animation

Figure 4A.2

Calculating the Economic Effect of Rent Controls

Once we have estimated equations for the demand and supply of rental housing, a diagram can guide our numerical estimates of the economic effects of rent control. Consumer surplus falls by an amount equal to the area of triangle B and increases by an amount equal to the area of rectangle A. Producer surplus falls by an amount equal to the sum of the areas of rectangle A and triangle C. The remaining producer surplus is equal to the area of triangle D. Deadweight loss is equal to the sum of the areas of triangles B and C.

We can calculate producer surplus in a similar way. Remember that producer surplus is the area above the supply curve and below the line representing market price. Because the supply curve is also a straight line, producer surplus in the figure is equal to the area of the triangle:

$$\frac{1}{2} \times 2,250,000 \times (2,500 - 769) = \$1,947,375,000.$$

This calculation tells us that the producer surplus in the market for rental apartments in New York City is about \$1.9 billion per month.

We can use the same type of analysis to measure the effect of rent control on consumer surplus, producer surplus, and economic efficiency. For instance, suppose the city imposes a rent ceiling of \$1,500 per month. Figure 4A.2 can help guide us as we measure the effect.

First, we can calculate the quantity of apartments that will actually be rented by substituting the rent ceiling of \$1,500 into the supply equation:

$$Q^S = -1,000,000 + (1,300 \times 1,500) = 950,000.$$

We also need to know the price on the demand curve when the quantity of apartments is 950,000. We can do this by substituting 950,000 for quantity in the demand equation and solving for price:

$$\begin{aligned} 950,000 &= 4,750,000 - 1,000P \\ P &= \frac{-3,800,000}{-1,000} = \$3,800. \end{aligned}$$

Compared with its value in competitive equilibrium, consumer surplus has been reduced by a value equal to the area of triangle B but increased by a value equal to the area of rectangle A. The area of triangle B is:

$$\frac{1}{2} \times (2,250,000 - 950,000) \times (3,800 - 2,500) = \$845,000,000,$$

and the area of rectangle A is Base \times Height, or:

$$(\$2,500 - \$1,500) \times (950,000) = \$950,000,000.$$

The value of consumer surplus in competitive equilibrium was \$2,531,250,000. As a result of the rent ceiling, it will be increased to:

$$(\$2,531,250,000 + 950,000,000) - \$845,000,000 = \$2,636,250,000.$$

Compared with its value in competitive equilibrium, producer surplus has been reduced by a value equal to the sum of the areas of triangle C and rectangle A. The area of triangle C is:

$$\frac{1}{2} \times (2,250,000 - 950,000) \times (2,500 - 1,500) = \$650,000,000.$$

We have already calculated the area of rectangle A as \$950,000,000. The value of producer surplus in competitive equilibrium was \$1,947,375,000. As a result of the rent ceiling, it will be reduced to:

$$\$1,947,375,000 - \$650,000,000 - \$950,000,000 = \$347,375,000.$$

The loss of economic efficiency, as measured by the deadweight loss, is equal to the value represented by the areas of triangles B and C, or:

$$\$845,000,000 + \$650,000,000 = \$1,495,000,000$$

The following table summarizes the results of the analysis (the values are in millions of dollars):

Consumer Surplus		Producer Surplus		Deadweight Loss	
Competitive Equilibrium	Rent Control	Competitive Equilibrium	Rent Control	Competitive Equilibrium	Rent Control
\$2,531	\$2,636	\$1,947	\$347	\$0	\$1,495

Qualitatively, we know that imposing rent control will make consumers better off, make landlords worse off, and decrease economic efficiency. The advantage of the analysis we have just gone through is that it puts dollar values on the qualitative results. We can now see how much consumers have gained, how much landlords have lost, and how great the decline in economic efficiency has been. Sometimes the quantitative results can be surprising. Notice, for instance, that after the imposition of rent control, the deadweight loss is actually much greater than the remaining producer surplus. Of course, these results are dependent on the numbers we chose for the demand and supply curve equations. Choosing different numbers would have changed the results.

Economists often study issues where the qualitative results of actions are apparent, even to non-economists. You don't have to be an economist to understand who wins and who loses from rent control or that if a company cuts the price of its product, its sales will increase. Business managers, policymakers, and the general public do, however, need economists to measure quantitatively the effects of different actions—including policies such as rent control—so that they can better assess the results of these actions.

Problems and Applications

- 4A.5** Suppose you have been hired to analyze the impact an imposition of a minimum wage has on employment in the labor market. Now suppose you estimate the demand

and supply functions for labor, where L stands for the quantity of labor (measured in thousands of workers) and W stands for the wage rate (measured in Euros per hour):

Demand: $L^D = 100 - 4W$

Supply: $L^S = 6W$

First, calculate the free market equilibrium wage and quantity of labor. Now suppose the proposed minimum wage is €12. How large will the surplus of labor in this market be?

Can Economic Policy Help Protect the Environment?

Suppose you work as a manager at a utility firm like We Energies, based in Milwaukee, Wisconsin. Your main job is to provide electric power to homes and businesses in your area. But unlike many other businesses, you must follow government regulation to determine *how* you produce your service. We Energies generates the electricity it sells mainly by burning coal. Most scientists believe that burning fossil fuels like coal generates carbon dioxide and other greenhouse gases that can increase global warming and cause potentially costly changes in climate.

In 2015, the Environmental Protection Agency (EPA) in President Barack Obama's administration announced the Clean Power Plan, which requires states to reduce power plant emissions to 32 percent below 2005 levels by 2030. Public opinion polls show that a large majority of people believe that the government should regulate greenhouse gases. Most economists agree that government policy should attempt to reduce these gases, but they disagree with the public about which government policies would be best. The public tends to support government rules that require firms to use particular methods to reduce pollution—for example, by requiring that automobile companies produce cars with better gas mileage. Many economists believe that using these *command-and-control policies* is a less economically efficient way to reduce pollution than is using *market-based policies* that rely on

economic incentives rather than on administrative rules.

A carbon tax is an example of a market-based policy. If the government taxes oil, coal, and other carbon-based fuels that generate carbon dioxide when burned, households and firms will have an economic incentive to reduce their use of those fuels. Government policies to reduce pollution, including the carbon tax, have been controversial, however. Some businesses oppose the carbon tax because they believe it will raise their costs of production. Other businesses view the carbon tax favorably, particularly in comparison with command-and-control policies that they see as more costly and less effective. The Pacific Gas and Electric Company, a utility based in California, has noted “the flexibility and power of market incentives to promote a cleaner environment and more sustainable economy.”

As we will see in this chapter, economic analysis plays an important role in the debate over environmental policies.

Economics in Your Life

What's the “Best” Level of Pollution?

Policymakers debate alternative approaches for achieving the goal of reducing carbon dioxide emissions. But how do we know the “best” level of carbon emissions? If carbon dioxide emissions hurt the environment, should the government take action to eliminate them completely? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 231** at the end of this chapter.

Pollution is a part of economic life. Consumers create air pollution by burning gasoline to power their cars and natural gas to heat their homes. Firms create air pollution when they produce electricity, pesticides, or plastics, among other products. Utilities such as electric power plants produce sulfur dioxide when they burn coal to generate electricity. Sulfur dioxide contributes to acid rain, which can damage trees, crops, and buildings. The burning of fossil fuels generates carbon dioxide and other greenhouse gases that can increase global warming.

Externality A benefit or cost that affects someone who is not directly involved in the production or consumption of a good or service.

Pollution is just one example of an *externality*. An **externality** is a benefit or cost that affects someone who is not directly involved in the production or consumption of a good or service. In the case of air pollution, there is a *negative externality* because, for example, people with asthma may bear a cost even though they were not involved in the buying or selling of the electricity that caused the pollution. *Positive externalities* are also possible. For instance, medical research can provide a positive externality because people who are not directly involved in producing it or paying for it can benefit.

A competitive market usually does a good job of producing the economically efficient quantity of a good or service, but not when there is an externality in the market. When there is a negative externality, the market may produce a quantity of the good that is greater than the efficient amount. When there is a positive externality, the market may produce a quantity that is less than the efficient amount. Government interventions in the economy—such as the price floors on agricultural products or price ceilings on rents we discussed in Chapter 4—can reduce economic efficiency. But, when there are externalities, government intervention may actually *increase* economic efficiency and enhance the well-being of society. The way in which government intervenes is important, however. Economists can help policymakers ensure that government programs are as efficient as possible.

In this chapter, we explore how best to deal with the problem of pollution and other externalities. We also look at *public goods*, such as national defense, which may not be produced at all unless the government produces them.

5.1 Externalities and Economic Efficiency

5.1

LEARNING OBJECTIVE: Identify examples of positive and negative externalities and use graphs to show how externalities affect economic efficiency.

When you consume a Big Mac, only you benefit, but when you consume a college education, other people also benefit. College-educated people are less likely to commit crimes, and by being better-informed voters, they are more likely to contribute to better government policies. So, although you capture most of the benefits of your college education, you do not capture all of them.

When you buy a Big Mac, the price you pay covers all of the cost McDonald's incurs in producing the Big Mac. When you buy electricity from a utility that burns coal and generates carbon dioxide, though, the price you pay covers some of the costs the utility incurs, but does not cover the cost of the damage carbon dioxide does to the environment.

So, there is a *positive externality* in the production of college educations because people who do not pay for them will nonetheless benefit from them. There is a *negative externality* in the generation of electricity. For example, if fish and wildlife have disappeared from a lake because of acid rain generated by a utility, people who live near the lake incur a cost—even though they may not purchase electricity from that utility.

The Effect of Externalities

Externalities interfere with the *economic efficiency* of a market equilibrium. A competitive market achieves economic efficiency by maximizing the sum of consumer surplus and producer surplus (see Chapter 4). *But that result holds only if there are no externalities in*

production or consumption. An externality can cause a difference between the *private cost* of production and the *social cost*.

- The **private cost** is the cost borne by the producer of a good or service.
- The **social cost** is the total cost of producing a good or service, and it is equal to the private cost plus any external cost, such as the cost of pollution.

Unless there is an externality, the private cost and the social cost are equal.

An externality can also cause a difference between the *private benefit* from consumption and the *social benefit*.

- The **private benefit** is the benefit received by the consumer of a good or service.
- The **social benefit** is the total benefit from consuming a good or service, and it is equal to the private benefit plus any external benefit, such as the benefit to others resulting from your college education.

Unless there is an externality, the private benefit and the social benefit are equal.

How a Negative Externality in Production Reduces Economic Efficiency Typically, economists assume that the producer of a good or service must bear all the costs of production. But we now know that this assumption is not always true. In the production of electricity, private costs are borne by the utility, but some external costs of pollution are borne by people who are not customers of the utility. The social cost of producing electricity is the sum of the private cost plus the external cost. Figure 5.1 shows the effect on the market for electricity of a negative externality in production.

S_1 is the market supply curve and represents only the private costs that utilities have to bear in generating electricity. Firms will supply an additional unit of a good or service only if they receive a price equal to the additional cost of producing that unit, so a supply curve represents the *marginal cost* of producing a good or service (see Chapter 4). If utilities also had to bear the cost of pollution, the supply curve would be S_2 , which represents the true marginal social cost of generating electricity. The equilibrium with price $P_{\text{Efficient}}$ and quantity $Q_{\text{Efficient}}$ is efficient. The equilibrium with price P_{Market} and quantity Q_{Market} is not efficient.

To see why, remember that an equilibrium is economically efficient if economic surplus—which is the sum of consumer surplus plus producer surplus—is at a

Private cost The cost borne by the producer of a good or service.

Social cost The total cost of producing a good or service, including both the private cost and any external cost.

Private benefit The benefit received by the consumer of a good or service.

Social benefit The total benefit from consuming a good or service, including both the private benefit and any external benefit.

MyEconLab Animation

Figure 5.1

The Effect of Pollution on Economic Efficiency

Because utilities do not bear the cost of acid rain, they produce electricity beyond the economically efficient level. Supply curve S_1 represents just the marginal private cost that the utility has to pay. Supply curve S_2 represents the marginal social cost, which includes the costs to those affected by acid rain. If the supply curve were S_2 rather than S_1 , market equilibrium would occur at price $P_{\text{Efficient}}$ and quantity $Q_{\text{Efficient}}$, the economically efficient level of output. But, when the supply curve is S_1 , the market equilibrium occurs at price P_{Market} and quantity Q_{Market} where there is a deadweight loss equal to the area of the yellow triangle. Because of the deadweight loss, this equilibrium is not efficient.

maximum (see Chapter 4). When economic surplus is at a maximum, the net benefit to society from the production of the good or service is at a maximum. With an equilibrium quantity of $Q_{\text{Efficient}}$, economic surplus is at a maximum, and the equilibrium is efficient. But, with an equilibrium quantity of Q_{Market} , economic surplus is reduced by the deadweight loss—equal to the yellow triangle in Figure 5.1—and the equilibrium is not efficient. The deadweight loss occurs because the supply curve is above the demand curve for the production of the units of electricity between $Q_{\text{Efficient}}$ and Q_{Market} . That is, the additional cost—including the external cost—of producing these units is greater than the marginal benefit to consumers, as represented by the demand curve. In other words, because of the cost of the pollution, economic efficiency would be improved if less electricity were produced.

We can conclude the following: *When there is a negative externality in producing a good or service, too much of the good or service will be produced at market equilibrium.*

How a Positive Externality in Consumption Reduces Economic Efficiency We have seen that a negative externality interferes with achieving economic efficiency. The same holds true for a positive externality. In earlier chapters, we assumed that the demand curve represents all the benefits that come from consuming a good. But a college education generates benefits that are not captured by the student receiving the education and so are not included in the market demand curve for college educations. Figure 5.2 shows the effect of a positive externality in consumption on the market for college educations.

If students receiving a college education could capture all its benefits, the demand curve would be D_2 , which represents the marginal social benefits. The actual demand curve is D_1 , however, which represents only the marginal private benefits received by students. The efficient equilibrium would occur at price $P_{\text{Efficient}}$ and quantity $Q_{\text{Efficient}}$. At this equilibrium, economic surplus is maximized. The market equilibrium, at price P_{Market} and quantity Q_{Market} , will not be efficient because the demand curve is above the supply curve for production of the units between Q_{Market} and $Q_{\text{Efficient}}$. That is, the marginal benefit—including the external benefit—of producing these units is greater than the marginal cost. As a result, there is a deadweight loss equal to the area of the yellow triangle. Because of the positive externality, economic efficiency would be improved if more college educations were produced.

We can conclude the following: *When there is a positive externality in consuming a good or service, too little of the good or service will be produced at market equilibrium.* **MyEconLab** **Concept Check**

Externalities and Market Failure

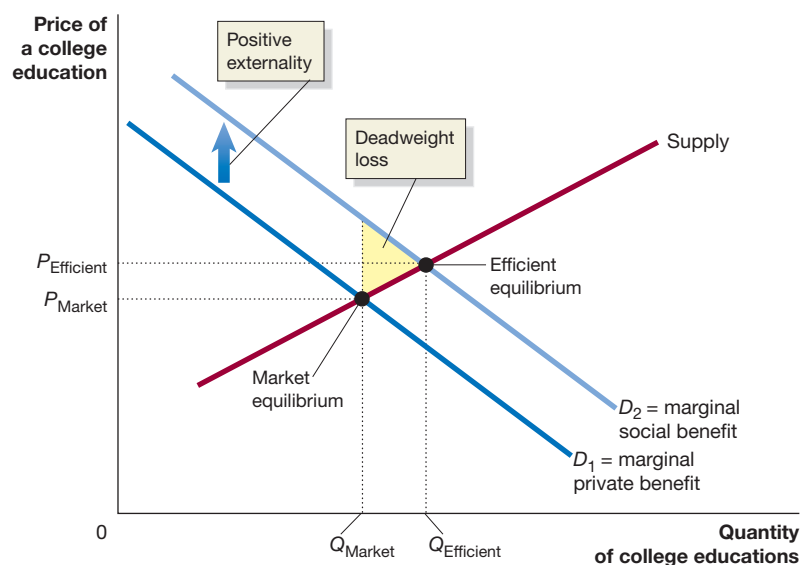

We have seen that because of externalities, the efficient level of output may not occur in either the market for electricity or the market for college educations. These are examples

MyEconLab Animation

Figure 5.2

The Effect of a Positive Externality on Economic Efficiency

People who do not consume college educations can still benefit from them. As a result, the marginal social benefit from a college education is greater than the marginal private benefit to college students. Because only the marginal private benefit is represented in the market demand curve D_1 , the quantity of college educations produced, Q_{Market} , is too low. If the market demand curve were D_2 instead of D_1 , the level of college educations produced would be $Q_{\text{Efficient}}$, which is the efficient level. At the market equilibrium of Q_{Market} , there is a deadweight loss equal to the area of the yellow triangle.

of **market failure**—situations in which the market fails to produce the efficient level of output. In Section 5.3, we will discuss possible solutions to problems of externalities. But, first, we need to consider why externalities occur.

MyEconLab Concept Check

Market failure A situation in which the market fails to produce the efficient level of output.

What Causes Externalities?

Governments need to guarantee *property rights* in order for a market system to function well (see Chapter 2). **Property rights** refer to the rights individuals or businesses have to the exclusive use of their property, including the right to buy or sell it. Property can be tangible or physical, such as a store or factory. Property can also be intangible, such as the right to an idea. Most of the time, the governments of the United States and other high-income countries do a good job of enforcing property rights, but in certain situations, property rights do not exist or cannot be legally enforced.

Consider the following situation: Lee owns land that includes a lake. A paper company wants to lease some of Lee's land to build a paper mill. The paper mill will discharge pollutants into Lee's lake. Because Lee owns the lake, he can charge the paper company the cost of cleaning up the pollutants. The result is that the cost of the pollution is a private cost to the paper company and is included in the price of the paper it sells. There is no externality, the efficient level of paper is produced, and there is no market failure.

Now suppose that the paper company again builds its paper mill on privately owned land but discharges its pollutants into a lake that is owned by the state government rather than by an individual. In the absence of any government regulations, the company can discharge pollutants into the lake without having to pay a fee. The cost of the pollution will be external to the company because it doesn't have to pay the cost of cleaning it up. The paper mill will produce a quantity of paper that is greater than the economically efficient level, and a market failure will occur. Or, suppose that Lee owns the lake, but the pollution is caused by acid rain generated by an electric utility hundreds of miles away. The law does not allow Lee to charge the electric utility for the damage caused by the acid rain. Even though someone is damaging Lee's property, he cannot enforce his property rights in this situation. Once again, there is an externality, and the market failure will result in too much electricity being produced.

If you buy a house, the government will protect your right to exclusive use of that house. No one else can use the house without your permission. Because of your property rights in the house, your private benefit from the house and the social benefit are the same. When you buy a college education, however, other people are able to benefit from it. You have no property right that will enable you to prevent them from benefiting or to charge them for the benefits they receive. As a result, there is a positive externality, and the market failure will result in too few college educations being supplied.

We can conclude the following: *Externalities and market failures result from incomplete property rights or from the difficulty of enforcing property rights in certain situations.*

5.2

Private Solutions to Externalities: The Coase Theorem

LEARNING OBJECTIVE: Discuss the Coase theorem and explain how private bargaining can lead to economic efficiency in a market with an externality.

As noted at the beginning of this chapter, government intervention may actually increase economic efficiency and enhance the well-being of society when externalities are present. It is also possible, however, for people to find private solutions to the problem of externalities.

Can the market cure market failure? In an influential article written in 1960, Ronald Coase formerly of the University of Chicago, winner of the 1991 Nobel Prize in Economics, argued that under some circumstances, private solutions to the problem of externalities will occur. To understand Coase's argument, we need to recognize that completely eliminating an externality usually is not economically efficient. Consider pollution, for example. There is, in fact, an *economically efficient level of pollution reduction*.

Property rights The rights individuals or businesses have to the exclusive use of their property, including the right to buy or sell it.

At first, this seems paradoxical. Pollution is bad, and you might think the efficient amount of a bad thing is zero. But it isn't zero.

The Economically Efficient Level of Pollution Reduction

Chapter 1 introduced the important idea that the optimal decision is to continue any activity up to the point where the marginal benefit equals the marginal cost. This idea applies to reducing pollution just as much as it does to other activities. Sulfur dioxide emissions contribute to smog and acid rain. As sulfur dioxide emissions—or any other type of pollution—decline, society benefits: Fewer trees die, fewer buildings are damaged, and fewer people suffer breathing problems. But, a key point is that the additional benefit—that is, the *marginal benefit*—received from eliminating another ton of sulfur dioxide *declines* as sulfur dioxide emissions are reduced. To see why, consider what happens if utilities generate electricity without attempting to reduce sulfur dioxide emissions. In this situation, many smoggy days will occur in the cities of the Midwest and Northeast. Even healthy people may experience breathing problems. As sulfur dioxide emissions are reduced, the number of smoggy days will fall, and healthy people will no longer experience breathing problems. Eventually, if sulfur dioxide emissions fall to low levels, people with asthma will no longer be affected. Further reductions in sulfur dioxide emissions will have little additional benefit. The same will be true of the other benefits from reducing sulfur dioxide emissions: As the reductions increase, the additional benefits from fewer buildings and trees being damaged and lakes polluted will decline.

Making the Connection MyEconLab Video

The Clean Air Act: How a Government Policy Reduced Infant Mortality

The following bar graphs show that the United States has made tremendous progress in reducing air pollution since Congress passed the Clean Air Act in 1970: By 2013, total emissions of the six main air pollutants had fallen dramatically. Over the same period, real U.S. gross domestic product (GDP)—which measures the value, corrected for inflation, of all the final goods and services produced in the country—more than tripled, energy consumption increased by half, and the number of miles traveled by all vehicles doubled.

Source: U.S. Environmental Protection Agency, "Air Quality Trends," www.epa.gov/airtrends/aqtrends.html.

As we have seen, when levels of pollution are high, the marginal benefit of reducing pollution is also high. We would expect, then, that the benefit of reducing air pollution in 1970 was much higher than the benefit from a proportional reduction in air pollution would be today, when the level of pollution is much lower. Kenneth Y. Chay of Brown University and Michael Greenstone of the University of Chicago have shown that the benefits from the reductions in air pollution that occurred in the period immediately after passage of the Clean Air Act were indeed large. Chay and Greenstone argue that the exposure of pregnant women to high levels of air pollution can be damaging to their unborn children, possibly by reducing lung functioning. This damage would increase the chance that the infant would die in the first weeks after being born. In the two years following passage of the Clean Air Act, there was a sharp reduction in air pollution and also in infant mortality. The decline was mainly due to a reduction in deaths within one month of birth. Of course, other factors may also have contributed to the decline in infant mortality, but Chay and Greenstone use statistical analysis to isolate the effect of the decline in air pollution. They conclude that “1,300 fewer infants died in 1972 than would have in the absence of the Clean Air Act.”

Further research by economists Adam Isen, of the U.S. Department of the Treasury, Maya Rossin-Slater, of the University of California, Santa Barbara, and W. Reed Walker, of the University of California, Berkeley, indicates that a reduction in exposure to pollution had a lasting effect on people who were small children at the time the act was passed. They estimate that as a result of improved health, the 1.5 million children born each year into the counties that had been the most polluted earn about \$4,300 more as adults than they would have if pollution had not been reduced.

What about the marginal cost to electric utilities of reducing pollution? To reduce sulfur dioxide emissions, utilities have to switch from burning high-sulfur coal to burning more costly fuel, or they have to install pollution control devices, such as scrubbers. As the level of pollution falls, further reductions become increasingly costly. Reducing emissions or other types of pollution to very low levels can require complex and expensive new technologies. For example, Arthur Fraas, formerly of the federal Office of Management and Budget, and Vincent Munley, of Lehigh University, have shown that the marginal cost of removing 97 percent of pollutants from municipal wastewater is more than twice as high as the marginal cost of removing 95 percent.

The *net benefit* to society from reducing pollution is equal to the difference between the benefit of reducing pollution and the cost. For us to maximize the net benefit to society, sulfur dioxide emissions—or any other type of pollution—should be reduced up to the point where the marginal benefit from another ton of reduction is equal to the marginal cost. Figure 5.3 illustrates this point.

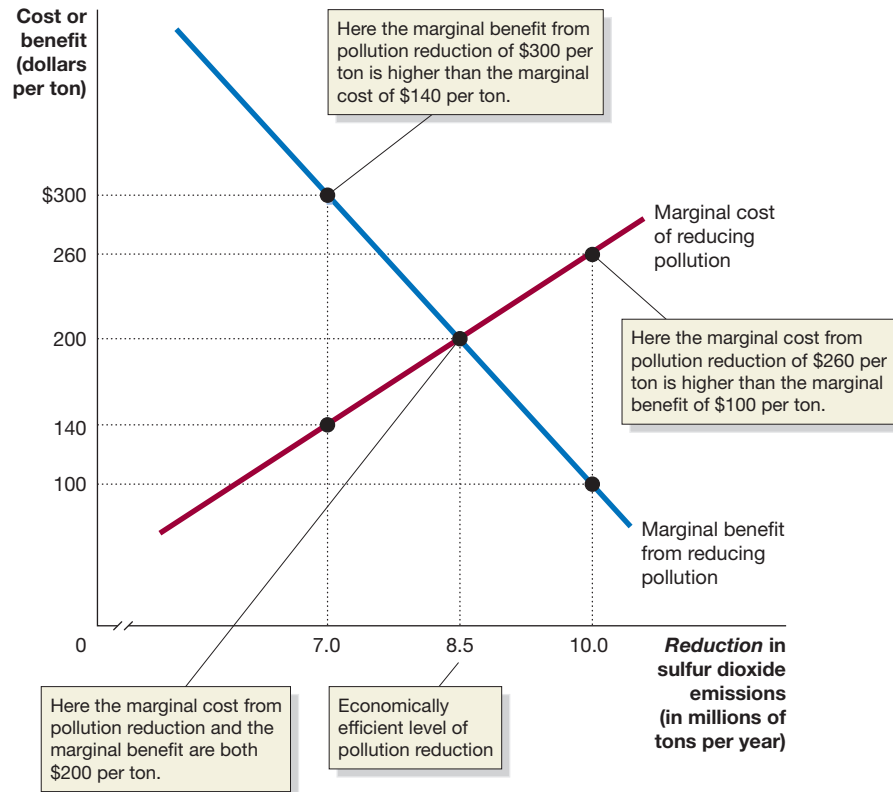

In Figure 5.3, we measure *reductions* in sulfur dioxide emissions on the horizontal axis. We measure the marginal benefit and marginal cost in dollars from eliminating another ton of sulfur dioxide emissions on the vertical axis. As reductions in pollution increase, the marginal benefit declines and the marginal cost increases. The economically efficient amount of pollution reduction occurs where the marginal benefit equals the marginal cost. The figure shows that, in this case, the economically efficient reduction of sulfur dioxide emissions is 8.5 million tons per year. In a program begun in 1990, this is the amount of reduction Congress decided should occur by 2010. At that level of emission reduction, the marginal benefit and the marginal cost of the last ton of sulfur dioxide emissions eliminated are both \$200 per ton. Suppose instead that the

MyEconLab Concept Animation

Figure 5.3

The Marginal Benefit from Pollution Reduction Should Equal the Marginal Cost

If the reduction of sulfur dioxide emissions is 7.0 million tons per year, the marginal benefit of \$300 per ton is greater than the marginal cost of \$140 per ton. Further reductions in emissions will increase the net benefit to society. If the reduction of sulfur dioxide emissions is 10.0 million tons, the marginal cost of \$260 per ton is greater than the marginal benefit of \$100 per ton. An increase in sulfur dioxide emissions will increase the net benefit to society. Only when the reduction is 8.5 million tons is the marginal benefit equal to the marginal cost. This level is the economically efficient level of pollution reduction.

emissions target was only 7.0 million tons. The figure shows that, at that level of reduction, the last ton of reduction has added \$300 to the benefits received by society, but it has added only \$140 to the costs of utilities. There has been a net benefit to society of \$160 from this ton of pollution reduction. In fact, the figure shows a net benefit to society from pollution reduction for every ton from 7.0 million to 8.5 million. Only when sulfur dioxide emissions are reduced by 8.5 million tons per year will marginal benefit fall enough and marginal cost rise enough that the two are equal.

Now suppose Congress had set the target for sulfur dioxide emissions reduction at 10 million tons per year. Figure 5.3 shows that the marginal benefit at that level of reduction falls to only \$100 per ton and the marginal cost rises to \$260 per ton. The last ton of reduction actually *reduces* the net benefit to society by \$160 per ton. In fact, every ton of reduction beyond 8.5 million reduces the net benefit to society.

To summarize:

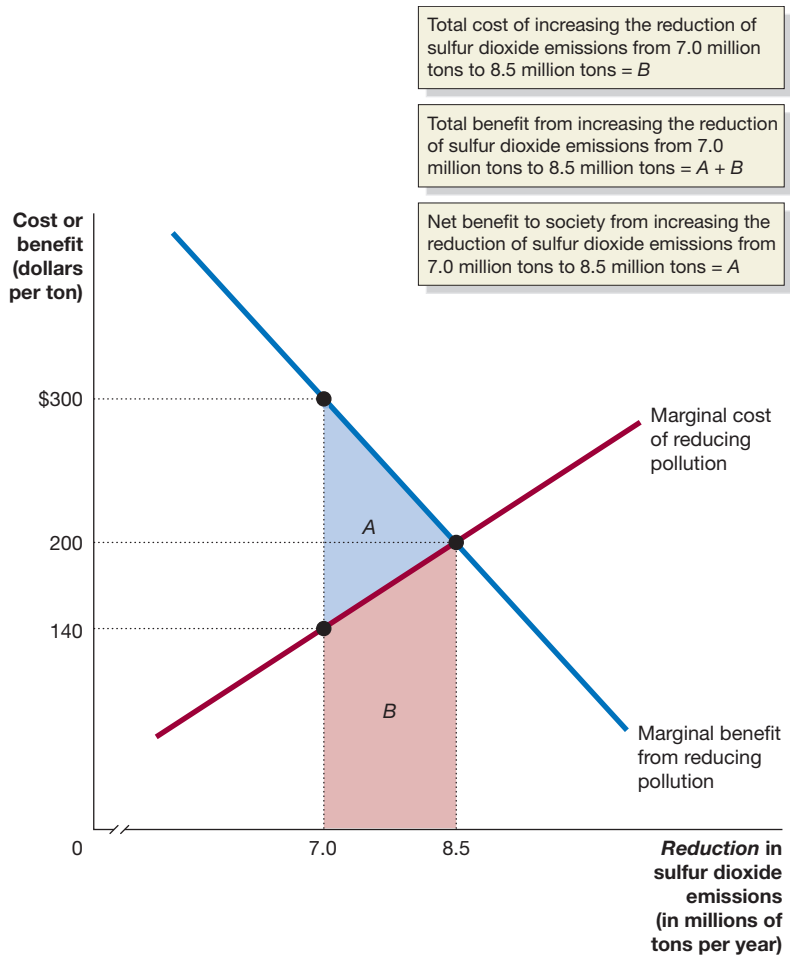

- If the marginal benefit of reducing pollution is greater than the marginal cost, further reductions will make society better off.
- If the marginal cost of reducing pollution is greater than the marginal benefit, further reductions will actually make society worse off.

The Basis for Private Solutions to Externalities

In arguing that private solutions to the problem of externalities were possible, Ronald Coase emphasized that when more than the optimal level of pollution is occurring, the benefits from reducing the pollution to the optimal level are greater than the costs. Figure 5.4 illustrates this point using the example of sulfur dioxide pollution.

The marginal benefit curve shows the additional benefit from each reduction in a ton of sulfur dioxide emissions. The area under the marginal benefit curve between the two emission levels is the *total* benefit received from reducing emissions from one level to another. For instance, in Figure 5.4, the total benefit from increasing the reduction in sulfur dioxide emissions from 7.0 million tons to 8.5 million tons is the sum of the areas

MyEconLab Concept Animation

Figure 5.4 The Benefits of Reducing Pollution to the Optimal Level Are Greater Than the Costs

Increasing the reduction in sulfur dioxide emissions from 7.0 million tons to 8.5 million tons results in total benefits equal to the sum of the areas of A and B under the marginal benefit curve. The total cost of this decrease in pollution is equal to the area of B under the marginal cost curve. The total benefits are greater than the total costs by an amount equal to the area of A . Because the total benefits from reducing pollution are greater than the total costs, it is possible for those receiving the benefits to pay for those receiving the benefits to arrive at a private agreement with polluters to pay them to reduce pollution.

of A and B . The marginal cost curve shows the additional cost from each reduction in a ton of emissions. The *total* cost of reducing emissions from one level to another is the area under the marginal cost curve between the two emission levels. The total cost from increasing the reduction in emissions from 7.0 million tons to 8.5 million tons is the area of B . The net benefit from reducing emissions is the difference between the total cost and the total benefit, which is equal to the area of A .

Don't Let This Happen to You

Remember That It's the *Net* Benefit That Counts

Why not *completely* eliminate anything unpleasant? As long as any person suffers any unpleasant consequences from air pollution, the marginal benefit of reducing air pollution will be positive. Therefore, removing every particle of air pollution will result in the largest *total* benefit to society. But removing every particle of air pollution is not optimal for the same reason that it is not optimal to remove every particle of dirt or dust from a room when cleaning it. The cost of cleaning your room is not just the price of the cleaning products but also the opportunity cost of your time. The more time you devote to cleaning your room, the less time you have for other activities. As you devote more and

more additional hours to cleaning your room, the alternative activities you have to give up are likely to increase in value, raising the opportunity cost of cleaning: Cleaning instead of watching television may not be too costly, but cleaning instead of eating any meals or getting any sleep is very costly. Optimally, you should eliminate dust and dirt in your room up to the point where the marginal benefit of the last dirt removed equals the marginal cost of removing it. Society should take the same approach to air pollution. The result is the largest *net* benefit to society.

MyEconLab Study Plan

Your Turn: Test your understanding by doing related problem 2.9 on page 234 at the end of this chapter.

In Figure 5.4, the benefits from further reductions in sulfur dioxide emissions are much greater than the costs. In the appendix to Chapter 1, we reviewed the formula for calculating the area of a triangle, which is $\frac{1}{2} \times \text{Base} \times \text{Height}$, and the formula for the area of a rectangle, which is $\text{Base} \times \text{Height}$. Using these formulas, we can calculate the value of the total benefits from the reduction in emissions and the value of the total costs. The value of the benefits ($A + B$) is \$375 million. The value of the costs (B) is \$255 million. If the people who would benefit from a reduction in pollution could get together, they could offer to pay the electric utilities \$255 million to reduce the pollution to the optimal level. After making the payment, they would still be left with a net benefit of \$120 million. In other words, a private agreement to reduce pollution to the optimal level is possible, without any government intervention.

MyEconLab Concept Check

Do Property Rights Matter?

In discussing the bargaining between the electric utilities and the people suffering the effects of the utilities' pollution, we assumed that the electric utilities were not legally liable for the damage they were causing. In other words, the property of the victims of pollution was not legally protected from damage, so the victims would have to pay the utilities to reduce the pollution. But would it make any difference if the utilities were legally liable for the damages? Surprisingly, as Coase was the first to point out, it does not matter for the amount of pollution reduction. The only difference would be that now the electric utilities would have to pay the victims of pollution for the right to pollute rather than the victims having to pay the utilities to reduce pollution. Because the marginal benefits and marginal costs of pollution reduction would not change, the bargaining should still result in the efficient level of pollution reduction—in this case, 8.5 million tons.

If the utilities are not legally liable, the victims of pollution have an incentive to pay the utilities to reduce pollution up to the point where the marginal benefit of the last ton of reduction is equal to the marginal cost. If the utilities are legally liable, they have an incentive to pay the victims of pollution to allow them to pollute up to the same point.

MyEconLab Concept Check

The Problem of Transactions Costs

Unfortunately, often polluters and the victims of pollution have difficulty arriving at a private solution to the problem of externalities. One important reason is that there are often both many polluters and many people suffering from the negative effects of pollution. Negotiating an agreement between the people suffering from pollution and the firms causing the pollution often fails because of the *transactions costs* involved.

Transactions costs are the costs in time and other resources that parties incur in the process of agreeing to and carrying out an exchange of goods or services. In this case, the transactions costs would include the time and other costs of negotiating an agreement, drawing up a binding contract, and monitoring the agreement. Unfortunately, when many people are involved, the transactions costs are often higher than the net benefits from reducing the externality. In that case, the cost of transacting ends up exceeding the gain from the transaction, and a private solution to an externality problem is not feasible.

MyEconLab Concept Check

The Coase Theorem

Coase's argument that private solutions to the problem of externalities are possible is summed up in the **Coase theorem**: *If transactions costs are low, private bargaining will result in an efficient solution to the problem of externalities.* We have seen the basis for the Coase theorem in the preceding example of pollution by electric utilities: Because the benefits from reducing an externality are often greater than the costs, private bargaining can lead to an efficient outcome. But we have also seen that this outcome will occur only if

Coase theorem The argument of economist Ronald Coase that if transactions costs are low, private bargaining will result in an efficient solution to the problem of externalities.

transactions costs are low, and in the case of pollution, they usually are not. In general, private bargaining is most likely to reach an efficient outcome if the number of parties bargaining is small.

In practice, we must add a couple of other qualifications to the Coase theorem. In addition to low transactions costs, private solutions to the problem of externalities will occur only if all parties to the agreement have full information about the costs and benefits associated with the externality, and all parties must be willing to accept a reasonable agreement. For example, if those suffering from the effects of pollution do not have information on the costs of reducing pollution, it is unlikely that the parties can reach an agreement. Unreasonable demands can also hinder an agreement. For instance, in the example of pollution by electric utilities, we saw that the total benefit of reducing sulfur dioxide emissions was \$375 million. Even if transactions costs are very low, if the utilities insist on being paid more than \$375 million to reduce emissions, no agreement will be reached because the amount paid exceeds the value of the reduction to those suffering from the emissions.

How Can You Defend Your Knees on a Plane Flight?

Imagine that you are on a plane peacefully using your laptop on the tray table. Then, with no warning, the person in front of you forcefully reclines her seat, banging your knees and—

much worse!—cracking the screen of your laptop. Unfortunately, this problem has become common. Until a few years ago, most seats in the coach section of airplanes had 32 inches of space from the front of one seat to the back of the seat in the next row. But airlines have been reconfiguring their planes to fit more seats. Today, many coach seats have only 29 inches of space, and those missing 3 inches can make a big difference, particularly if you have long legs!

Clearly there is an externality involved when someone reclines a seat. The person reclining gets the benefit of a more comfortable position, but as the person in the seat behind, you have to bear the cost of a seat reclining into your space. But is it your space? If you had a property right to the space, you could choose to make the person in front of you pay a fee to recline her chair. But the airlines own the space, and their policy is to allow people to recline their seats. The airlines' views became clear following incidents involving the Knee Defender, a device invented by Ira Goldman. When you slip Goldman's gadget over the bars on your tray table, it prevents the seat in front of you from being reclined. When fights broke out over the use of the gadget, most major U.S. airlines banned its use.

So, with the airlines having given passengers the right to recline their seats, what can you do if the person in front of you is squeezing your knees or making it impossible for you to use your laptop on your tray table? If the cost to you from these problems is greater than the benefit to the person in front of you from reclining, then there should be a payment that you can make to that person in exchange for not reclining. That's the solution that Josh Barro, a frequent flier and *New York Times* columnist, suggested: "If my reclining bothers you, you can pay me to stop." He was skeptical that many people really are bothered by having the seat in front of them reclined: "If they really cared that much, someone would have opened his wallet and paid me by now."

Applying Coase's theorem, Barro's analysis seems to be correct: If the cost to you from having the seat in front of yours reclined is greater than the benefit to the recliner, you should make a payment to the recliner. Because this outcome rarely occurs, people reclining must get a larger benefit than the cost imposed on people behind them. But economist Donald Marron of the Urban Institute argues that this analysis holds only if we assume that the transactions costs of negotiating an agreement are low. If many people don't like the idea of negotiating with a stranger about a

If you were on a plane, would you be willing to pay the passenger in front of you to not recline her seat?

payment for not reclining a seat, then the transactions costs might be too high for the efficient outcome to occur.

Ronald Coase passed away in 2013, so we may never know how he dealt with the issue of someone in front of him reclining his or her seat.

5.3 Government Policies to Deal with Externalities

LEARNING OBJECTIVE: Analyze government policies to achieve economic efficiency in a market with an externality.

When private solutions to externalities are not feasible, how should the government intervene? British economist A. C. Pigou of Cambridge University was the first to analyze market failure systematically.

Imposing a Tax When There Is a Negative Externality

Pigou argued that to deal with a negative externality in production, the government should impose a tax equal to the cost of the externality. The effect of such a tax is shown in Figure 5.5, which reproduces the negative externality from acid rain shown in Figure 5.1 on page 207.

By imposing a tax on the production of electricity equal to the cost of acid rain, the government will cause electric utilities to *internalize* the externality. As a consequence, the cost of the acid rain will become a private cost borne by the utilities, and the supply curve for electricity will shift from S_1 to S_2 . The result will be a decrease in the equilibrium output of electricity from Q_{Market} to the efficient level, $Q_{\text{Efficient}}$. The price consumers pay for electricity will rise from P_{Market} —which does not include the cost of acid

MyEconLab Animation

Figure 5.5

When There Is a Negative Externality, a Tax Can Lead to the Efficient Level of Output

Because utilities do not bear the cost of acid rain, they produce electricity beyond the economically efficient level. If the government imposes a tax equal to the cost of acid rain, the utilities will internalize the externality. As a consequence, the supply curve will shift up, from S_1 to S_2 . The market equilibrium quantity changes from Q_{Market} , where an inefficiently high level of electricity is produced, to $Q_{\text{Efficient}}$, the economically efficient equilibrium quantity. The price of electricity will rise from P_{Market} —which does not include the cost of acid rain—to $P_{\text{Efficient}}$ —which does include the cost. Consumers pay the price $P_{\text{Efficient}}$, while producers receive the price P , which is equal to $P_{\text{Efficient}}$ minus the amount of the tax.

MyEconLab Animation

Figure 5.6

When There Is a Positive Externality, a Subsidy Can Bring about the Efficient Level of Output

People who do not consume college educations can benefit from them. As a result, the social benefit from a college education is greater than the private benefit to college students. If the government pays a subsidy equal to the external benefit, students will internalize the externality. The subsidy will cause the demand curve to shift up, from D_1 to D_2 . As a result, the market equilibrium quantity will shift from Q_{Market} , where an inefficiently low level of college educations is supplied, to $Q_{\text{Efficient}}$, the economically efficient equilibrium quantity. Producers receive the price $P_{\text{Efficient}}$, while consumers pay the price P , which is equal to $P_{\text{Efficient}}$ minus the amount of the subsidy.

rain—to $P_{\text{Efficient}}$ —which does include the cost. Producers will receive a price P , which is equal to $P_{\text{Efficient}}$ minus the amount of the tax.

Providing a Subsidy When There Is a Positive Externality

Pigou also reasoned that the government can deal with a positive externality in consumption by giving consumers a subsidy, or payment, equal to the value of the externality. The effect of such a subsidy is shown in Figure 5.6, which reproduces the positive externality from college education shown in Figure 5.2 on page 208.

By paying college students a subsidy equal to the external benefit from a college education, the government will cause students to *internalize* the externality. That is, the external benefit from a college education will become a private benefit received by college students, and the demand curve for college educations will shift from D_1 to D_2 . The equilibrium number of college educations supplied will increase from Q_{Market} to the efficient level, $Q_{\text{Efficient}}$. Producers receive the price $P_{\text{Efficient}}$, while consumers pay the price P , which is equal to $P_{\text{Efficient}}$ minus the amount of the subsidy. In fact, the government does heavily subsidize college educations. All states have government-operated universities that charge tuitions well below the cost of providing the education. The state and federal governments also provide students with grants and low-interest loans that subsidize college educations. The economic justification for these programs is that college educations provide an external benefit to society.

Should the Government Tax Cigarettes and Soda?

Generally, governments use Pigovian taxes to deal with negative externalities in *production*. Governments also impose taxes—sometimes called *sin taxes*—on products such as cigarettes and alcohol. Some policymakers have argued that these products generate negative externalities in *consumption*, so a tax on them can increase economic efficiency. Recently, several cities have considered taxing sweetened soda, on the grounds that they cause a negative externality by raising medical costs. Just as governments can deal with a positive externality in consumption by giving consumers a subsidy, they can deal with a negative externality by imposing a tax.

As the following figure shows, by imposing a tax on soda, the government will cause consumers to internalize the externality. That is, the external cost to drinking soda will become a private cost paid by consumers. Because consumers now have to pay a tax on soda, at every quantity they are willing to pay less than they would have without the tax, so the demand curve for soda will shift down by the amount of the tax, from D_1 to D_2 . The equilibrium quantity of sodas consumed will decrease from Q_{Market} to the efficient level, $Q_{\text{Efficient}}$. (Note that as we saw in Chapter 4, pages 186–188, we get the same result whether the government imposes a tax on the buyers of a good or on the sellers.)

But do people actually cause a negative externality by smoking and drinking sweetened sodas? It might seem that they don't, because consumers of cigarettes and sodas bear the costs of any health problems they experience. In fact, though, the higher medical expenses from treating the complications of cigarette smoking or obesity are not paid entirely by the smokers or soda drinkers. A smoker who receives health insurance through his employer may increase the costs of that insurance, which all the workers at the firm will pay. Similarly, taxpayers partly pay for the health care of someone who is over age 65 and is enrolled in the federal government's Medicare program. The costs of medical care that smokers or soda drinkers do not pay themselves represent a negative externality.

There is a complication to this conclusion, however: Smokers and people who are obese tend to die early. This tragic outcome means that smokers and the obese may have been paying taxes to help pay for Social Security and Medicare benefits that they will never receive. They may also have made payments into company and public employee pension plans and purchased long-term care insurance, but they may not have lived long enough to receive many pension payments or to have spent time in a nursing home. So, there are offsetting effects: While alive, smokers and obese people may impose costs on others who bear the expense of their higher medical costs, but because they are likely to die early, they provide a financial gain to recipients of Social Security, Medicare, company and public employee pension plans, and purchasers of long-term care insurance.

W. Kip Viscusi of Vanderbilt University has studied the case of tobacco smoking and concluded that the external costs and benefits roughly offset each other, meaning that there doesn't appear to be a significant negative externality from smoking. Studies of obesity have arrived at somewhat conflicting results: A study of obesity in the Netherlands found that the cost savings from premature death offset the additional

lifetime medical costs of obese people. But another study using U.S. data found that obesity did lead to a net increase in lifetime medical costs, even taking into account the shorter average life spans of obese people.

There may also be costs to smoking and obesity beyond additional medical costs. Smokers may inflict costs on others because of secondhand smoke or because smoking during pregnancy can lead to low birth weights and other health problems for babies. Airlines have noted that they spend more on fuel costs because of the increasing weight of passengers.

Economists and policymakers continue to debate whether the government should use taxes to deal with negative externalities in consumption.

Solved Problem 5.3

MyEconLab Interactive Animation

Dealing with the Externalities of Car Driving

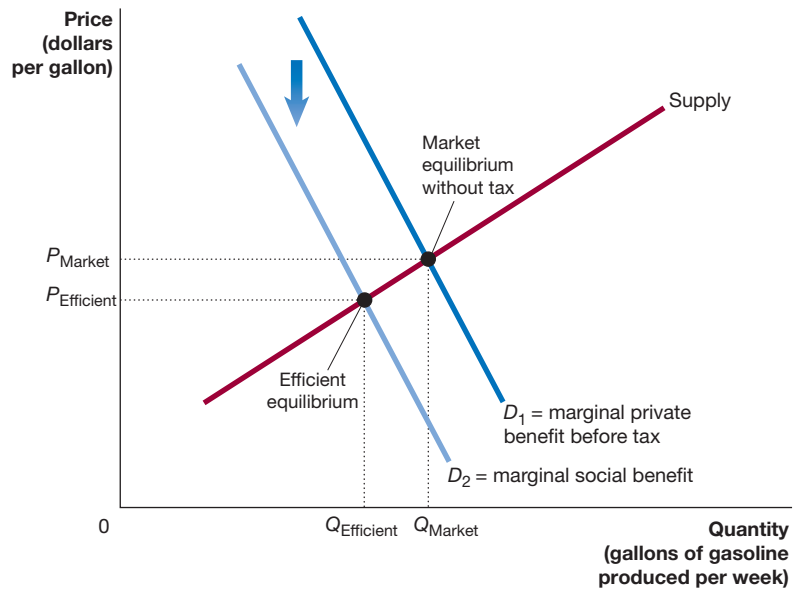

When you drive a car, you generate several negative externalities: You cause some additional air pollution, you increase the chances that other drivers will have an accident, and you cause some additional congestion on roads, causing other drivers to spend more time in traffic. Ian Parry of the International Monetary Fund and Kenneth Small of the University of California, Irvine, have estimated that these external costs amount to about \$1.00 per gallon of gasoline. Taxes on gasoline vary by state and currently average about \$0.50 per gallon.

- Draw a graph showing the gasoline market. Indicate the efficient equilibrium quantity and the market equilibrium quantity.
- Given the information in this problem, if the government wanted to bring about the efficient level of gasoline production, how large a tax should the government impose on gasoline? Will the price consumers pay for gasoline rise by the full amount of the tax? Briefly explain using your graph from part (a).

Solving the Problem

Step 1: Review the chapter material. This problem is about the government using a tax to deal with a negative externality, so you may want to review the section “Government Policies to Deal with Externalities,” which begins on page 216.

Step 2: Answer part (a) by drawing a graph of the gasoline market. In this case, the tax is levied on the consumption of gasoline rather than on its production, so your graph should show the demand curve representing marginal social benefit being below the demand curve showing marginal private benefit. (Of course, the government actually collects the tax from sellers rather than from consumers, but we get the same result whether the government imposes a tax on the buyers of a good or on the sellers.) Your graph should also show the market equilibrium quantity of gasoline, Q_{Market} , being greater than the efficient equilibrium quantity, $Q_{\text{Efficient}}$.

Step 3: Answer part (b) by explaining the size of the necessary tax, indicating the tax on your graph from part (a), and explaining the effect of the tax on the equilibrium price. If Parry and Small are correct that the external cost from consuming gasoline is \$1.00 per gallon, then the tax per gallon should be raised from \$0.50 to \$1.00 per gallon. You should show the effect of the increase in the tax on your graph.

The graph shows that although the tax shifts down the demand curve for gasoline, the price consumers pay increases by less than the amount of the tax. To see this, note that the price consumers pay rises from P_{Market} to P , which is smaller than the per gallon tax, which equals the vertical distance between $P_{\text{Efficient}}$ and P .

Because Pigou was the first economist to propose using government taxes and subsidies to deal with externalities, they are sometimes referred to as **Pigovian taxes and subsidies**. Note that a Pigovian tax eliminates deadweight loss and improves economic efficiency, unlike most taxes, which are intended simply to raise revenue and can reduce consumer surplus and producer surplus and create a deadweight loss (see Chapter 4). In fact, one reason that economists support Pigovian taxes as a way to deal with negative externalities is that the government can use the revenues raised by Pigovian taxes to lower other taxes that reduce economic efficiency. For instance, the Canadian province of British Columbia has enacted a Pigovian tax on carbon dioxide emissions and uses the revenue raised to reduce personal income taxes.

Pigovian taxes and subsidies

Government taxes and subsidies intended to bring about an efficient level of output in the presence of externalities.

Command-and-Control versus Market-Based Approaches

Although the federal government has sometimes used taxes and subsidies to deal with externalities, it has more frequently used a *command-and-control approach* to deal with pollution. A **command-and-control approach** to reducing pollution involves the government imposing quantitative limits on the amount of pollution firms are allowed to emit or requiring firms to install specific pollution control devices. For example, in the 1980s, the federal government required auto manufacturers such as Ford and General Motors to install catalytic converters to reduce auto emissions on all new automobiles.

Congress could have used a command-and-control approach to achieve its goal of reducing sulfur dioxide emissions by 8.5 million tons per year by 2010. However, this approach would not have been an economically efficient solution to the problem because utilities can have very different costs of reducing sulfur dioxide emissions. Some utilities that already used low-sulfur coal could reduce emissions further only at a high cost. Other utilities, particularly those in the Midwest, were able to reduce emissions at a lower cost.

Congress decided to use a market-based approach to reducing sulfur dioxide emissions by setting up a *cap-and-trade system* of tradable emission allowances. The federal government gave allowances to utilities equal to the total target amount of sulfur dioxide emissions. The utilities were then free to buy and sell the allowances. An active market where the allowances could be bought and sold was conducted on the Chicago Mercantile Exchange. Utilities that could reduce emissions at low cost did so and sold their allowances. Utilities that could only reduce emissions at high cost bought allowances.

Using tradable emission allowances to reduce acid rain was a success in that it made it possible for utilities to meet Congress's emissions goal at a much lower cost than expected. Just before Congress enacted the allowances program in 1990, the Edison Electric Institute estimated that the cost to utilities of complying with the program would be \$7.4 billion by 2010. By 1994, the federal government's General Accounting Office estimated that the cost would be less than \$2 billion. In practice, the cost was almost 90 percent less than the initial estimate, or only about \$870 million.

MyEconLab **Concept Check**

Command-and-control approach

A policy that involves the government imposing quantitative limits on the amount of pollution firms are allowed to emit or requiring firms to install specific pollution control devices.

The End of the Sulfur Dioxide Cap-and-Trade System

The dollar value of the total benefits of reducing sulfur dioxide emissions turned out to be at least 25 times as large as the costs. Despite its successes, however, the sulfur dioxide cap-and-trade system had effectively ended by 2013. Over the years, research showed that the amount of illnesses caused by sulfur dioxide emissions was greater than had been thought. In response to these findings, President George W. Bush proposed legislation lowering the cap on sulfur dioxide emissions, but Congress did not pass the legislation. Court rulings kept the Environmental Protection Agency (EPA) from using regulations to set up a new trading system for sulfur dioxide allowances with a lower cap. As a result, the EPA reverted to the previous system of setting limits on sulfur dioxide emissions at the state or individual power plant level.

Because nationwide trading of emission allowances was no longer possible, the allowances lost their value. Many economists continue to believe that using market-based policies, such as the sulfur dioxide cap-and-trade system, is an efficient way to deal with the externalities of pollution. But in the end, any policy requires substantial political support to be enacted and maintained.

MyEconLab **Concept Check**

Are Tradable Emission Allowances Licenses to Pollute?

Tradable emission allowances face a political problem because some environmentalists have criticized them for being “licenses to pollute.” These environmentalists argue that just as the government does not issue licenses to rob banks or drive drunk, it should not issue licenses to pollute. But, this criticism ignores one of the central lessons of economics: Because resources are scarce, trade-offs exist. Resources that are spent on reducing one type of pollution are not available to reduce other types of pollution or for any other use. Because reducing acid rain using tradable emission allowances cost utilities \$870 million per year, rather than \$7.4 billion, as originally estimated, society saved more than \$6.5 billion per year.

Can a Carbon Tax Reduce Global Warming?

In the past 35 years, the global temperature has increased about 0.75 degree Fahrenheit (or 0.40 degree Celsius) compared with the average for the period between 1951 and 1980. The following graph shows changes in temperature in the years since 1880.

Source: NASA, Goddard Institute for Space Studies, data.giss.nasa.gov/gistemp/tabledata_v3/GLB.Ts.txt.

Over the centuries, global temperatures have gone through many long periods of warming and cooling. Nevertheless, many scientists are convinced that the recent warming trend is not part of the natural fluctuations in temperature but is primarily caused by the burning of fossil fuels, such as coal, natural gas, and petroleum. Burning these fuels releases carbon dioxide, which accumulates in the atmosphere as a “greenhouse gas.” Greenhouse gases cause some of the heat released from the earth to be reflected back, increasing temperatures. Annual carbon dioxide emissions increased from about 50 million metric tons of carbon in 1850 to 1,600 million metric tons in 1950 and to nearly 9,900 million metric tons in 2013.

If greenhouse gases continue to accumulate in the atmosphere, according to some estimates, global temperatures could increase by 3 degrees Fahrenheit or more during the next 100 years. Such an increase in temperature could lead to significant changes in climate, which might result in more hurricanes and other violent weather conditions, disrupt farming in many parts of the world, and lead to increases in sea levels, which could result in flooding in coastal areas.

Although most economists and policymakers agree that emitting carbon dioxide results in a significant negative externality, there has been extensive debate over which

policies should be adopted. Part of the debate arises from disagreements about how rapidly global warming is likely to occur and what the economic cost will be. In addition, carbon dioxide emissions are a worldwide problem; sharp reductions in carbon dioxide emissions only in the United States and Europe, for instance, would not be enough to stop global warming. But coordinating policy across countries has proven difficult. Finally, policymakers and economists debate the relative effectiveness of different policies.

Governments have used several approaches to reducing carbon dioxide emissions. The European Union has established a cap-and-trade system under which each country issues emission allowances that can be freely traded among firms in different countries. The European Parliament, though, has been unwilling to reduce the number of allowances available over time, making it unclear how the system could be used to further reduce carbon dioxide emissions.

As mentioned in the chapter opener, in 2015, the Obama administration introduced the Clean Power Plan, which requires states to reduce power plant emissions to 32 percent below 2005 levels by 2030. To meet the goals, utilities, such as We Energies in Wisconsin, need to close coal-burning electric power plants and replace them with plants burning natural gas or powered by alternative energy sources, such as wind or solar. Some economists and policymakers are unsure whether the plan's goals can be met without disrupting the country's power supply.

Many economists favor a carbon tax as a market-based policy to reduce carbon dioxide emissions. Economists working at federal government agencies have estimated that the marginal social cost of carbon dioxide emissions is about \$21 per ton. The Congressional Budget Office estimates that a Pigovian tax equal to that amount would reduce carbon dioxide emissions in the United States by about 8 percent over 10 years. The federal government would collect about \$1.2 trillion in revenues from the tax over the same period. One government study indicates that 87 percent of a carbon tax would be borne by consumers in the form of higher prices for gasoline, electricity, natural gas, and other goods. For example, a \$21 per ton carbon tax would increase the price of gasoline by about \$0.18 to \$0.20 per gallon. Because lower-income households spend a larger fraction of their incomes on gasoline than do higher-income households, they would bear a proportionally larger share of the tax. Most proposals for a carbon tax include a way of refunding to lower-income households some part of their higher tax payments.

As of late 2015, it seemed doubtful that Congress would pass a carbon tax. The debate over policies to deal with global warming is likely to continue for many years.

Four Categories of Goods

LEARNING OBJECTIVE: Explain how goods can be categorized on the basis of whether they are rival or excludable and use graphs to illustrate the efficient quantities of public goods and common resources.

We can explore further the question of when the market is likely to succeed in supplying the efficient quantity of a good by understanding that goods differ on the basis of whether their consumption is *rival* and *excludable*:

- **Rivalry** occurs when one person's consumption of a unit of a good means no one else can consume it. If you consume a Big Mac, for example, no one else can consume it.
- **Excludability** means that anyone who does not pay for a good cannot consume it. If you don't pay for a Big Mac, McDonald's can exclude you from consuming it. The consumption of a Big Mac is therefore rival and excludable.

Rivalry The situation that occurs when one person's consumption of a unit of a good means no one else can consume it.

Excludability The situation in which anyone who does not pay for a good cannot consume it.

MyEconLab Animation

Figure 5.7

Four Categories of Goods

Goods and services can be divided into four categories on the basis of whether people can be excluded from consuming them and whether they are rival in consumption. A good or service is rival in consumption if one person consuming a unit of the good means that another person cannot consume that unit.

	Excludable	Nonexcludable
Rival	Private Goods <i>Examples:</i> Big Macs Running shoes	Common Resources <i>Examples:</i> Tuna in the ocean Public pasture land
Nonrival	Quasi-Public Goods <i>Examples:</i> Cable TV Toll road	Public Goods <i>Examples:</i> National defense Court system

The consumption of some goods, however, can be either *nonrival* or *nonexcludable*:

- Nonrival means that one person's consumption does not interfere with another person's consumption.
- Nonexcludable means that it is impossible to exclude others from consuming the good, whether they have paid for it or not.

Figure 5.7 shows four possible categories into which goods can fall. We next consider each of the four categories:

Private good A good that is both rival and excludable.

Public good A good that is both nonrival and nonexcludable.

Free riding Benefiting from a good without paying for it.

Common resource A good that is rival but not excludable.

1. A **private good** is both rival and excludable. Food, clothing, haircuts, and many other goods and services fall into this category. One person's consuming a unit of these goods keeps other people from consuming that unit, and no one can consume these goods without buying them. Although we didn't state it explicitly, when we analyzed the demand and supply for goods and services in earlier chapters, we assumed that the goods and services were all private goods.
2. A **public good** is both nonrival and nonexcludable. Public goods are often, although not always, supplied by a government rather than by private firms. The classic example of a public good is national defense. Your consuming national defense does not interfere with your neighbor consuming it, so consumption is nonrival. You also cannot be excluded from consuming it, whether you pay for it or not. No private firm would be willing to supply national defense because everyone can consume national defense whether they pay for it or not. The behavior of consumers in this situation is called **free riding** because individuals benefit from a good—in this case, national defense—without paying for it.
3. A *quasi-public good* is excludable but not rival. An example is cable television. People who do not pay for cable television do not receive it, but one person watching it doesn't prevent other people from watching it. Another example is a toll road. Anyone who doesn't pay the toll doesn't get on the highway, but one person using the highway doesn't interfere with someone else using the highway (unless so many people are using the highway that it becomes congested). Goods that fall into this category are called *quasi-public goods*.
4. A **common resource** is rival but not excludable. Forest land in many poor countries is a common resource. If one person cuts down a tree, no one else can use that tree. But if no one has a property right to the forest, no one can be excluded from using it. As we will discuss in more detail later, people often overuse common resources.

We analyzed the demand and supply for private goods in earlier chapters. For the remainder of this chapter, we focus on the categories of public goods and common resources. To determine the optimal quantity of a public good, we have to modify our usual demand and supply analysis to take into account that a public good is both nonrival and nonexcludable.

The Demand for a Public Good

We can determine the market demand curve for a good or service by adding up the quantity of the good demanded by each consumer at each price. To keep things simple, let's consider the case of a market with only two consumers. Figure 5.8 shows that the market demand curve for hamburgers depends on the individual demand curves of Jill and Joe.

MyEconLab Animation

Figure 5.8 Constructing the Market Demand Curve for a Private Good

The market demand curve for private goods is determined by adding horizontally the quantity of the good demanded at each price by each consumer. For instance, in panel (a), Jill demands 2 hamburgers when the price

is \$4.00, and in panel (b), Joe demands 4 hamburgers when the price is \$4.00. So, a quantity of 6 hamburgers and a price of \$4.00 is a point on the market demand curve in panel (c).

At a price of \$4.00, Jill demands 2 hamburgers per week and Joe demands 4. Adding horizontally, the combination of a price of \$4.00 per hamburger and a quantity demanded of 6 hamburgers will be a point on the market demand curve for hamburgers. Similarly, adding horizontally at a price of \$1.50, we have a price of \$1.50 and a quantity demanded of 11 as another point on the market demand curve. A consumer's demand curve for a good represents the marginal benefit the consumer receives from the good, so when we add together the consumers' demand curves, we have not only the market demand curve but also the marginal social benefit curve for this good, assuming that there is no externality in consumption.

How can we find the demand curve or marginal social benefit curve for a public good? Once again, for simplicity, assume that Jill and Joe are the only consumers. Unlike with a private good, where Jill and Joe can end up consuming different quantities, with a public good, they will consume *the same quantity*. Suppose that Jill owns a service station on an isolated rural road, and Joe owns a car dealership next door. These are the only two businesses around for miles. Both Jill and Joe are afraid that unless they hire a security guard at night, their businesses may be burgled. Like national defense, the services of a security guard are in this case a public good: Once hired, the guard will be able to protect both businesses, so the good is nonrival. It also will not be possible to exclude either business from being protected, so the good is nonexcludable.

To arrive at a demand curve for a public good, we don't add quantities at each price, as with a private good. Instead, we add the price each consumer is willing to pay for each quantity of the public good. This value represents the total dollar amount consumers as a group would be willing to pay for that quantity of the public good. In other words, to find the demand curve, or marginal social benefit curve, for a private good, we add the demand curves of individual consumers horizontally; for public goods, we add individual demand curves vertically. Figure 5.9 shows how the marginal social benefit curve for security guard services depends on the individual demand curves of Jill and Joe.

The figure shows that Jill is willing to pay \$8 per hour for the guard to provide 10 hours of protection per night. Joe would suffer a greater loss from a burglary, so he is willing to pay \$10 per hour for the same amount of protection. Adding the dollar amount that each is willing to pay gives us a price of \$18 per hour and a quantity of 10 hours as a point on the marginal social benefit curve for security guard services. The figure also shows that because Jill is willing to spend \$4 per hour for 15 hours of guard services and Joe is willing to pay \$5, a price of \$9 per hour and a quantity of 15 hours is another point on the marginal social benefit curve for security guard services.

MyEconLab Animation

Figure 5.9

Constructing the Demand Curve for a Public Good

To find the demand curve for a public good, we add up the price at which each consumer is willing to purchase each quantity of the good. In panel (a), Jill is willing to pay \$8 per hour for a security guard to provide 10 hours of protection. In panel (b), Joe is willing to pay \$10 for that level of protection. Therefore, in panel (c), the price of \$18 per hour and the quantity of 10 hours will be a point on the demand curve for security guard services.

The Optimal Quantity of a Public Good

We know that to achieve economic efficiency, a good or service should be produced up to the point where the sum of consumer surplus and producer surplus is maximized, or, alternatively, where the marginal social cost equals the marginal social benefit. Therefore, the optimal quantity of security guard services—or any other public good—will occur where the marginal social benefit curve intersects the supply curve. As with private goods, in the absence of an externality in production, the supply curve represents the marginal social cost of supplying the good. Figure 5.10 shows that the optimal quantity of security guard services supplied is 15 hours, at a price of \$9 per hour.

Will the market provide the economically efficient quantity of security guard services? One difficulty is that the individual preferences of consumers, as shown by their demand curves, are not revealed in this market. This difficulty does not arise with private goods because consumers must reveal their preferences in order to purchase private goods. If the market price of Big Macs is \$4.00, Joe either reveals that he is willing to pay that much by

MyEconLab Animation

Figure 5.10

The Optimal Quantity of a Public Good

buying it or he does without it. In our example, neither Jill nor Joe can be excluded from consuming the services provided by a security guard once either hires one, and, therefore, neither has an incentive to reveal her or his preferences. In this case, though, with only two consumers, it is likely that private bargaining will result in an efficient quantity of the public good. This outcome is not likely for a public good—such as national defense—that is supplied by the government to millions of consumers.

Governments sometimes use *cost–benefit analysis* to determine what quantity of a public good should be supplied. For example, before building a dam on a river, the federal government will attempt to weigh the costs against the benefits. The costs include the opportunity cost of other projects the government cannot carry out if it builds the dam. The benefits include improved flood control or new recreational opportunities on the lake formed by the dam. However, for many public goods, including national defense, the government does not use a formal cost–benefit analysis. Instead, the quantity of national defense supplied is determined by a political process involving Congress and the president. Even here, of course, Congress and the president realize that trade-offs are involved: The more resources used for national defense, the fewer resources are available for other public or private goods.

Determining the Optimal Level of Public Goods

Suppose, once again, that Jill and Joe run businesses that are next door to each other on an isolated road, and both need a security guard. Their demand schedules for security guard services are as follows:

Joe		Jill	
Price (dollars per hour)	Quantity (hours of protection)	Price (dollars per hour)	Quantity (hours of protection)
\$20	0	\$20	1
18	1	18	2
16	2	16	3
14	3	14	4
12	4	12	5
10	5	10	6
8	6	8	7
6	7	6	8
4	8	4	9
2	9	2	10

The supply schedule for security guard services is as follows:

Price (dollars per hour)	Quantity (hours of protection)
\$8	1
10	2
12	3
14	4
16	5
18	6
20	7
22	8
24	9

- a. Draw a graph that shows the optimal level of security guard services. Be sure to label the curves on the graph.
- b. Briefly explain why 8 hours of security guard protection is not an optimal quantity.

Solving the Problem

Step 1: Review the chapter material. This problem is about determining the optimal level of public goods, so you may want to review the section “The Optimal Quantity of a Public Good,” which begins on page 226.

Step 2: Begin by deriving the demand curve or marginal social benefit curve for security guard services. To calculate the marginal social benefit of guard services, we need to add the prices that Jill and Joe are willing to pay at each quantity:

Demand or Marginal Social Benefit	
Price (dollars per hour)	Quantity (hours of protection)
\$38	1
34	2
30	3
26	4
22	5
18	6
14	7
10	8
6	9

Step 3: Answer part (a) by plotting the demand (marginal social benefit) and supply (marginal social cost) curves. The graph shows that the optimal level of security guard services is 6 hours.

Step 4: Answer part (b) by explaining why 8 hours of security guard protection is not an optimal quantity. For each hour beyond 6, the supply curve is above the demand curve. Therefore, the marginal social benefit received will be less than the marginal social cost of supplying these hours. This results in a deadweight loss and a reduction in economic surplus.

MyEconLab Study Plan

Common Resources

In England during the Middle Ages, each village had an area of pasture, known as a *commons*, on which any family in the village was allowed to graze its cows or sheep without charge. Of course, the grass one family's cow ate was not available for another family's cow, so consumption was rival. But every family in the village had the right to use the commons, so it was nonexcludable. Without some type of restraint on usage, the commons would be overgrazed. To see why, consider the economic incentives facing a family that was thinking of buying another cow and grazing it on the commons. The family would gain the benefits from increased milk production, but adding another cow to the commons would create a negative externality by reducing the amount of grass available for the cows of other families. Because this family—and the other families in the village—did not take this negative externality into account when deciding whether to add another cow to the commons, too many cows would be added. The grass on the commons would eventually be depleted, and no family's cow would get enough to eat.

The Tragedy of the Commons The tendency for a common resource to be overused is called the **tragedy of the commons**. The forests in many poor countries are a modern example. When a family chops down a tree in a public forest, it takes into account the benefits of gaining firewood or wood for building, but it does not take into account the costs of deforestation. Haiti, for example, was once heavily forested. Today, 80 percent of the country's forests have been cut down, primarily to be burned to create charcoal for heating and cooking. Because the mountains no longer have tree roots to hold the soil, heavy rains now often lead to devastating floods.

Figure 5.11 shows that with a common resource such as wood from a forest, the efficient level of use, $Q_{\text{Efficient}}$, is determined by the intersection of the demand curve, which represents the marginal social benefit received by consumers, and S_2 , which

Tragedy of the commons The tendency for a common resource to be overused.

MyEconLab Animation

Figure 5.11

Overuse of a Common Resource

For a common resource such as wood from a forest, the efficient level of use, $Q_{\text{Efficient}}$, is determined by the intersection of the demand curve, which represents the marginal social benefit received by consumers, and S_2 , which represents the marginal social cost of cutting the wood. Because each individual tree cutter ignores the external cost, the equilibrium quantity of wood cut is Q_{Actual} , which is greater than the efficient quantity. At the actual equilibrium level of output, there is a deadweight loss, equal to the area of the yellow triangle.

represents the marginal social cost of cutting the wood. As in our discussion of negative externalities, the social cost is equal to the private cost of cutting the wood plus the external cost. In this case, the external cost represents the fact that the more wood each person cuts, the less wood there is available for others and the greater the deforestation, which increases the chances of floods. Because each individual tree cutter ignores the external cost, the equilibrium quantity of wood cut is Q_{Actual} , which is greater than the efficient quantity. At the actual equilibrium level of output, there is a deadweight loss, equal to the area of the yellow triangle in Figure 5.11.

Is There a Way out of the Tragedy of the Commons? Notice that our discussion of the tragedy of the commons is very similar to our earlier discussion of negative externalities. The source of the tragedy of the commons is the same as the source of negative externalities: lack of clearly defined and enforced property rights. For instance, suppose that instead of being held as a collective resource, a piece of pastureland is owned by one person. That person will take into account the effect of adding another cow on the grass available to cows already using the pasture. As a result, the optimal number of cows will be placed on the pasture. Over the years, most of the commons lands in England were converted to private property. Most of the forestland in Haiti and other developing countries is actually the property of the government. The failure of the government to protect the forests against trespassers or convert them to private property is the key reason those forests are overused.

In some situations, though, enforcing property rights is *not* feasible. An example is the oceans. Because no country owns the oceans beyond its own coastal waters, the fish and other resources of the ocean will remain a common resource. In situations in which enforcing property rights is not feasible, two types of solutions to the tragedy of the commons are possible:

1. If the geographic area involved is limited and the number of people involved is small, access to the commons can be restricted through community norms and laws. If the geographic area or the number of people involved is large, legal restrictions on access to the commons are required. For instance, the tragedy of the commons was avoided in the Middle Ages by traditional limits on the number of animals each family was allowed to put on the common pasture. Although these traditions were not formal laws, they were usually enforced adequately by social pressure.
2. If the geographic area or the number of people involved is large, legal restrictions on access to the commons are required. These restrictions can take several different forms, including taxes, quotas, and tradable permits. By setting a tax equal to the external cost, governments can ensure that the efficient quantity of a resource is used. In the United States, the government has used quotas to limit access to pools of oil that are beneath property owned by many different persons. The quotas specify the quantity of oil that can be pumped during a given period of time.

What's the "Best" Level of Pollution?

At the beginning of this chapter, we asked you to think about what is the "best" level of carbon emissions. Conceptually, this is a straightforward question to answer: The efficient level of carbon emissions is the level for which the marginal benefit of reducing carbon emissions exactly equals the marginal cost of reducing carbon emissions. In practice, however, this question is very difficult to answer. For example, scientists disagree about how much carbon emissions are contributing to climate change and what the damage from climate change will be. In addition, the cost of reducing carbon emissions depends on the method of reduction used. As a result, neither the marginal cost curve nor the marginal benefit curve for reducing carbon emissions is known with certainty. This uncertainty makes it difficult for policymakers to determine the economically efficient level of carbon emissions and is the source of much of the current debate. In any case, economists agree that the total cost of *completely* eliminating carbon emissions is much greater than the total benefit.

Conclusion

Government interventions in the economy, such as imposing price ceilings and price floors, can reduce economic efficiency. But in this chapter, we have seen that the government plays an important role in the economy when the absence of well-defined and enforceable property rights keeps the market from operating efficiently. For instance, because no one has a property right to clean air, in the absence of government intervention, firms will produce too great a quantity of products that generate air pollution. We have also seen that public goods are nonrival and nonexcludable, so the government often supplies them.

Externalities and Economic Efficiency, pages 206–209

LEARNING OBJECTIVE: Identify examples of positive and negative externalities and use graphs to show how externalities affect economic efficiency.

Summary

An **externality** is a benefit or cost to parties who are not involved in a transaction. Pollution and other externalities in production cause a difference between the **private cost** borne by the producer of a good or service and the **social cost**, which includes any external cost, such as the cost of pollution. An externality in consumption causes a difference between the **private benefit** received by the consumer and the **social benefit**, which includes any external benefit. If externalities exist in production or consumption, the market will not produce the optimal level of a good or service. This outcome is referred to as **market failure**. Externalities arise when property rights do not exist or cannot be legally enforced. **Property rights** are the rights individuals or businesses have to the exclusive use of their property, including the right to buy or sell it.

Review Questions

- 1.1 What is an externality? Give an example of a positive externality, and give an example of a negative externality.
- 1.2 When will the private cost of producing a good differ from the social cost? Give an example. When will the private benefit from consuming a good differ from the social benefit? Give an example.
- 1.3 How are externalities related to the efficiency of competitive market equilibrium?
- 1.4 How do market failures relate to the necessity of government intervention in certain markets?
- 1.5 Briefly explain the relationship between property rights and the existence of externalities.

Problems and Applications

- 1.6 Externalities are costs and benefits that affect people who are not directly involved in the production or consumption of a good or service. In some cases the existence of

externalities is evident; for example, when individuals use motor vehicles they consume a transportation service and at the same time they contribute towards air pollution. However, in other cases things are not so clear; for example, studying at a university is an activity that can be thought to have a number of different externalities. Would you be able to list at least two externalities that you have observed at your university? Briefly explain your choices.

- 1.7 Yellowstone National Park is in bear country. The National Park Service, at its Yellowstone Web site, states the following about camping and hiking in bear country:

Do not leave packs containing food unattended, even for a few minutes. Allowing a bear to obtain human food even once often results in the bear becoming aggressive about obtaining such food in the future. Aggressive bears present a threat to human safety and eventually must be destroyed or removed from the park. Please obey the law and do not allow bears or other wildlife to obtain human food.

What negative externality does obtaining human food pose for bears? What negative externality do bears obtaining human food pose for future campers and hikers?

- 1.8 Every year at the beginning of flu season, many people, including the elderly, get a flu shot to reduce their chances of contracting the flu. One result is that people who do *not* get a flu shot are less likely to contract the flu.
 - a. What type of externality (negative or positive) arises from getting a flu shot?
 - b. On the graph that follows, show the effects of this externality by drawing in and labeling any additional curves that are needed and by labeling

the efficient quantity and the efficient price of flu shots. Label the area representing deadweight loss in this market.

- 1.9** Boris Johnson, the Mayor of London, has decided to support a project that will create a single segregated cycle lane along Embankment to link Hyde Park with Tower Hill. Business representatives have complained that the bike lanes will increase congestion for cars by reducing traffic lanes, with negative effects on businesses. Campaigners in favour of the cycle lane, instead, have supported the project and the reduction in negative externalities that it will create. What externalities are associated with driving? How do these externalities affect the debate over whether big cities should install more cycle lanes?

- 1.10** In a study at a large state university, students were randomly assigned roommates. Researchers found that, on average, males assigned to roommates who reported drinking alcohol in the year before entering college earned GPAs one-quarter point lower than those assigned to non-drinking roommates. For males who drank frequently before college, being assigned to a roommate who also drank frequently before college reduced their GPAs by two-thirds of a point. Draw a graph showing the price of alcohol and the quantity of alcohol consumption on college campuses. Include in the graph the demand for drinking and the private and social costs of drinking. Label any deadweight loss that arises in this market.

- 1.11** Tom and Jacob are college students. Each of them will probably get married later and have two or three children. Each knows that if he studies more in college, he’ll get a better job and earn more money. Earning more will enable them to spend more on their future families for things such as orthodontia, nice clothes, admission to expensive colleges, and travel. Tom thinks about the benefits to his

potential children when he decides how much studying to do. Jacob doesn’t.

- What type of externality arises from studying?
- Draw a graph showing this externality, contrasting the responses of Tom and Jacob. Who studies more? Who acts more efficiently? Briefly explain.

- 1.12** In recent years, companies have used fracking, or hydraulic fracturing, in drilling for oil and natural gas that previously could not be profitably recovered. According to an article in the *New York Times*, “horizontal drilling has enabled engineers to inject millions of gallons of high-pressure water directly into layers of shale to create the fractures that release the gas. Chemicals added to the water dissolve minerals, kill bacteria that might plug up the well, and insert sand to prop open the fractures.” Experts are divided about whether fracking results in significant pollution, but some people worry that chemicals used in fracking might lead to pollution of underground supplies of water used by households and farms.

- First, assume that fracking causes no significant pollution. Use a demand and supply graph to show the effect of fracking on the market for natural gas.
- Now assume that fracking does result in pollution. On your graph from part (a), show the effect of fracking. Be sure to carefully label all curves and all equilibrium points.
- In your graph in part (b), what has happened to the efficient level of output and the efficient price in the market for natural gas compared with the situation before fracking? Can you be certain that the efficient level of output and the efficient price have risen or fallen as a result of fracking? Briefly explain.

- 1.13** In an article in the agriculture magazine *Choices*, Oregon State University economist JunJie Wu made the following observation about the conversion of farmland to urban development:

Land use provides many economic and social benefits, but often comes at a substantial cost to the environment. Although most economic costs are figured into land use decisions, most environmental externalities are not. These environmental “externalities” cause a divergence between private and social costs for some land uses, leading to an inefficient land allocation. For example, developers may not bear all the environmental and infrastructural costs generated by their projects. Such “market failures” provide a justification for private conservation efforts and public land use planning and regulation.

What does the author mean by *market failures* and *inefficient land allocation*? Explain why the author describes inefficient land allocation as a market failure. Illustrate your argument with a graph showing the market for land to be used for urban development.

5.2 Private Solutions to Externalities: The Coase Theorem, pages 209–216

LEARNING OBJECTIVE: Discuss the Coase theorem and explain how private bargaining can lead to economic efficiency in a market with an externality.

Summary

Externalities and market failures result from incomplete property rights or from the difficulty of enforcing property rights in certain situations. When an externality exists and the efficient quantity of a good is not being produced, the total cost of reducing the externality is usually less than the total benefit. **Transactions costs** are the costs in time and other resources that parties incur in the process of agreeing to and carrying out an exchange of goods or services. According to the **Coase theorem**, if these costs are low, private bargaining will result in an efficient solution to the problem of externalities.

Government Policies to Deal with Externalities, pages 216–223

LEARNING OBJECTIVE: Analyze government policies to achieve economic efficiency in a market with an externality.

Summary

When private solutions to externalities are unworkable, the government sometimes intervenes. One way to deal with a negative externality in production is to impose a tax equal to the cost of the externality. The tax causes the producer of the good to internalize the externality. The government can deal with a positive externality in consumption by giving consumers a subsidy, or payment, equal to the value of the externality. Government taxes and subsidies intended to bring about an efficient level of output in the presence of externalities are called **Pigovian taxes and subsidies**. Although the federal government has sometimes used subsidies and taxes to deal with externalities, in dealing with pollution it has more often used a command-and-control approach. A **command-and-control approach** involves the government imposing quantitative limits on the amount of pollution allowed or requiring firms to install specific pollution control devices. Direct pollution controls of this type are not economically efficient, however. As a result, economists generally prefer reducing pollution by using market-based policies.

Review Questions

- 3.1 Define a Pigovian tax. Briefly list and explain the problems related to the implementation of the tax.
- 3.2 What does it mean for a producer or consumer to internalize an externality? What would cause a producer or consumer to internalize an externality?
- 3.3 Why do most economists prefer tradable emission allowances to the command-and-control approach to pollution?

Problems and Applications

- 3.4 A heated debate has taken place in the North of England regarding the possibility of the government to provide licenses to private companies to extract shale gas using fracking. “Fracking is the process of drilling down into the earth before a high-pressure water mixture is directed at the rock to release the gas inside. Water, sand, and chemicals are injected into the rock at high pressure which allows the gas to flow out to the head of the well.”
 - a. What do you think the added costs associated with the fracking process may be?
 - b. Do you think that the price the U.K. government will charge the shale gas companies should include the added costs related to the drilling technique? Briefly explain.

- 3.6 The price of solar panels has decreased by 70 percent. In 2014, the U.K. government decided to withdraw subsidies from large-scale solar farms. The Solar Trade Association has criticized this decision and expressed the view that subsidies would be necessary to ensure that the solar industry could reach a position to compete with fossil fuels.
 - a. Are there externalities involved in the market for solar panels that would require a government subsidy to achieve an economically efficient outcome? Briefly explain.
 - b. Every homeowner in the United Kingdom can also install solar panels and receive a payment from the grid for the electricity produced and introduced in the network. Effectively, this system (called feed-in-tariff) allows private residents to install solar panels at no cost. Does that fact make the case for a government subsidy of the production of solar energy stronger or weaker? Briefly explain.

- 3.7 A column in the *New York Times* has the headline, “Should We Tax People for Being Annoying?”
 - a. Do annoying people cause a negative externality? Should they be taxed? Do crying babies on a bus or plane cause a negative externality? Should the babies (or their parents) be taxed?
 - b. Do people who plant flowers and otherwise have beautiful gardens visible from the street cause a positive externality? Should these people receive a government subsidy?
 - c. Should every negative externality be taxed? Should every positive externality be subsidized? How might the government decide whether using Pigovian taxes and subsidies is appropriate?

- 3.8 Is government intervention, for instance in the form of subsidies, always justified in the case of positive externalities? Is the fact that all activities create benefits that may not be appropriable by their creators a debatable statement? Briefly discuss the reasons for your answer.
- 3.9 (Related to the **Making the Connection on page 217**) Researchers at the University of Cambridge have shown

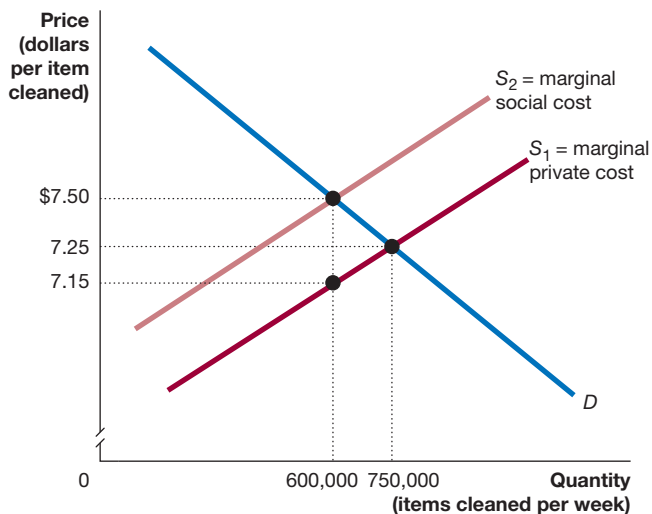

that lack of exercise may have a mortality effect twice as much as obesity.

- a. What do researchers and policy makers mean by “mortality effect”? Why would the mortality effect of obesity being smaller than the mortality effect of lack of exercise result in obesity having a larger external cost?
- b. Government interventions to induce people to eat better and be more active (such as turning roads into cycle/pedestrian lanes, increasing tariff on petrol and diesel or introducing sugar taxes on sodas) tend to be less politically popular than taxes on cigarettes. Why might the general public be more willing to support cigarette taxes than soda taxes?

3.10 (Related to Solved Problem 5.3 on page 219) Solved Problem 5.3 contains the statement “Of course, the government actually collects the tax from sellers rather than from consumers, but we get the same result whether the government imposes a tax on the buyers of a good or on the sellers.” Demonstrate that this statement is correct by solving the problem, assuming that the increase in the tax on gasoline shifts the supply curve rather than the demand curve.

3.11 (Related to Solved Problem 5.3 on page 219) The fumes from dry cleaners can contribute to air pollution. Suppose the following graph illustrates the situation in the dry cleaning market.

- a. Explain how a government can use a tax on dry cleaning to bring about the efficient level of production. What should the value of the tax be?
- b. How large is the deadweight loss (in dollars) from excessive dry cleaning, according to the figure?

3.12 (Related to Solved Problem 5.3 on page 219) Companies that produce toilet paper bleach the paper to make it white. Some paper plants discharge the bleach into rivers and lakes, causing substantial environmental damage. Suppose the following graph illustrates the situation in the toilet paper market.

Explain how the federal government can use a tax on toilet paper to bring about the efficient level of production. What should be the value of the tax?

3.13 When announcing the new budget, George Osborne, the U.K. Chancellor of the Exchequer, has described the introduction of new penalties to fight tax evasion and tax avoidance in the United Kingdom. When a tax payer evades taxes, for example declaring a lower level of taxable income, and is found guilty of tax evasion by the auditor, they will have to pay a penalty proportional to the tax evaded.

- a. Is there an economically efficient amount of tax evasion? Briefly explain.
- b. Briefly explain whether a penalty for evading taxes proportion to the amount of taxes evaded is a Pigovian tax of the type discussed in this chapter.

3.14 The graph on the next page illustrates the situation in the dry cleaning market, assuming that the marginal social cost of the pollution increases as the quantity of items cleaned per week increases. The graph includes two demand curves: one for a smaller city, D_S , and the other for a larger city, D_L .

- Explain why the marginal social cost curve has a different slope than the marginal private cost curve.
- What tax per item cleaned will achieve economic efficiency in the smaller city? In the larger city? Explain why the efficient tax is different in the two cities.

3.15 (Related to the Chapter Opener on page 205) The U.K. government has decided to increase the carbon tax from £9.55 per tonne to £18.08 per tonne from April 2015.

- Why might a carbon tax be a better approach to reducing carbon dioxide emissions than an approach that relies on directly regulating how power is generated in a state?
- Why might a command-and-control approach to pollution control be more politically popular than an approach that relies on taxes? Include in your answer a brief discussion of the difference between the normative and positive analysis of this policy issue.

3.16 (Related to the Making the Connection on page 210) Think about the economically efficient level of pollution reduction, which has been mentioned in this Chapter in relation to the global warming problem.

- Is it possible for us to fully understand the costs that are related to global warming?
- Why does the fact that world governments are willing to start taking serious and concrete measures to tackle the problem of global warming, within the next few years, seem unrealistic?

Four Categories of Goods, pages 223–230

LEARNING OBJECTIVE: Explain how goods can be categorized on the basis of whether they are rival or excludable and use graphs to illustrate the efficient quantities of public goods and common resources.

Summary

There are four categories of goods: private goods, public goods, quasi-public goods, and common resources. **Private goods** are both rival and excludable. **Rivalry** means that when one person consumes a unit of a good, no one else can consume that unit. **Excludability** means that anyone who does not pay for a good cannot consume it. **Public goods** are both nonrival and nonexcludable. Private firms are usually not willing to supply public goods because of free riding. **Free riding** involves benefiting from a good without paying for it. **Quasi-public goods** are excludable but not rival. **Common resources** are rival but not excludable. The **tragedy of the commons** refers to the tendency for a common resource to be overused. The tragedy of the commons results from a lack of clearly defined and enforced property rights. We find the market demand curve for a private good by adding the quantity of the good demanded by each consumer at each price. We find the demand curve for a public good by adding vertically the price each consumer would be willing to pay for each quantity of the good. The optimal quantity of a public good occurs where the demand curve intersects the curve representing the marginal cost of supplying the good.

Do People Respond to Changes in the Price of Gasoline?

When you drive into a Shell or an Exxon service station to buy gas, you may think you are dealing with an outlet owned by a gigantic multinational oil company. Most likely, though, the service station is actually owned by a local businessperson who buys oil from a large oil company but is responsible for running the business. In fact, in the United States more than half the owners of service stations or convenience stores that sell gas own just one store. These local businesspeople have experienced a bumpy ride over the past few years, as gasoline prices have been on a roller coaster.

In the summer of 2008, the average price of a gallon of gasoline was \$4.00. By the end of the year, it had fallen to around \$1.50. It rose back to nearly \$4.00 by 2011 before falling to below \$2.00 at the beginning of 2015 and then rising again. Service station and convenience store owners usually gain from falling gasoline prices because the price the oil companies charge them—the wholesale price of gasoline—falls faster than the price they charge to their customers—the retail price. For instance, as gasoline prices fell in late 2014, the gap between the wholesale and retail prices of gasoline increased from about 26 cents per gallon to about 37 cents. This gain was only temporary, however, because competition among service stations eventually forced down the retail price.

But do fluctuations in gas prices have much effect on sales of gasoline? Some

people argue that consumers don't vary the quantity of gas they buy as the price fluctuates because the number of miles they need to drive to get to work or school or to run errands is roughly constant. An article in the *Wall Street Journal* quoted a spokesperson for the American Automobile Association (AAA) as saying, "Falling gasoline prices haven't historically led to more driving." Actual consumer behavior contradicts this observation. For example, in December 2014, when the average price of gasoline was \$2.50 per gallon, U.S. consumers bought about 7 percent more gasoline than they did during April 2014, when the average price of gasoline was \$3.60 per gallon.

All businesses have a financial incentive to determine how much their sales will increase as prices fall. Governments also have an incentive to determine how consumers will react if the price of a product such as gasoline rises following a tax increase. In this chapter, we will explore what determines the responsiveness of the quantity demanded and the quantity supplied to changes in the market price.

Stoll and Jeff Bennett, "U.S. Auto Buyers Spend to Trade Up," *Wall Street Journal*, May 1, 2015; Nicole Friedman, "Why Gas Stations Are Cleaning Up Even As Prices Plummet," *Wall Street Journal*, October 23, 2014; "US Transit Rides at 58-Year High While Gas Prices Fall," *boston.com*, March 9, 2015; and data on gasoline prices and gasoline consumption from the U.S. Energy Information Administration.

Economics in Your Life

How Much Do Gas Prices Matter to You?

What factors would make you more or less responsive to price when purchasing gasoline? Have you responded differently to price changes during different periods of your life? Why do consumers seem to respond more to changes in gas prices at a particular service station but seem less sensitive when gas prices rise or fall at all service stations? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 265** at the end of this chapter.

Elasticity A measure of how much one economic variable responds to changes in another economic variable.

Whether you manage a service station, a restaurant, or a coffee shop, you need to know how an increase or a decrease in the price of your products will affect the quantity consumers are willing to buy. We know that cutting the price of a good increases the quantity demanded and that raising the price reduces the quantity demanded. But the critical question is: *How much* will the quantity demanded change as a result of a price increase or decrease? Economists use the concept of **elasticity** to measure how one economic variable—such as the quantity demanded—responds to changes in another economic variable—such as the price. For example, the responsiveness of the quantity demanded of a good to changes in its price is called the *price elasticity of demand*. Knowing the price elasticity of demand allows you to compute the effect of a price change on the quantity demanded. This knowledge is important to a business in determining the price that will maximize profit

In addition to a good's price, consumer income and the prices of related goods also affect the quantity of the good that consumers demand. As a manager, you can also apply the concept of elasticity to measure the responsiveness of demand to these other variables. There are many economic issues where we are also interested in the responsiveness of the quantity supplied of a good to changes in its price, which is called the *price elasticity of supply*.

In this chapter, we will see that elasticity is an important concept not just for business managers but for policymakers as well. For example, if the government wants to discourage teenage smoking, it can raise the price of cigarettes by increasing the tax on them. If policymakers know the price elasticity of demand for cigarettes, they can calculate how many fewer packs of cigarettes teenagers will demand at a higher price.

6.1 The Price Elasticity of Demand and Its Measurement

LEARNING OBJECTIVE: Define price elasticity of demand and understand how to measure it.

We know from the law of demand that when the price of a product falls, the quantity demanded of the product increases. But the law of demand tells firms only that the demand curves for their products slope downward. It is more useful to have a measure of the responsiveness of the quantity demanded to a change in price. This measure is called the **price elasticity of demand**.

Price elasticity of demand The responsiveness of the quantity demanded to a change in price, measured by dividing the percentage change in the quantity demanded of a product by the percentage change in the product's price.

Measuring the Price Elasticity of Demand

We might measure the price elasticity of demand by using the slope of the demand curve because the slope tells us how much quantity changes as price changes, but this approach has a drawback: The measurement of slope is sensitive to the units chosen for quantity and price. For example, suppose a \$1 per gallon decrease in the price of gasoline leads to an increase in the quantity demanded from 10.1 million gallons to 10.2 million gallons per day. The change in quantity is 0.1 million gallons, and the change in price is $-\$1$, so the slope is $0.1/-1 = -0.1$. But:

- If we measure price in cents, rather than in dollars, the slope is $0.1/-100 = -0.001$.
- If we measure price in dollars and gallons in thousands, instead of millions, the slope is $100/-1 = -100$.
- If we measure price in cents and gallons in thousands, the slope is $100/-100 = -1$.

Clearly, the value we compute for the slope can change dramatically, depending on the units we use for quantity and price.

To avoid this confusion over units, economists use *percentage changes* when measuring the price elasticity of demand. Percentage changes are not dependent on units of measurement. (For a review of calculating percentage changes, see the appendix to Chapter 1.) No matter what units we use to measure the quantity of gasoline, 10 percent more gasoline is 10 percent more gasoline. Therefore, the price elasticity of demand is measured by dividing the percentage change in the quantity demanded by the percentage change in the product's price. Or:

$$\text{Price elasticity of demand} = \frac{\text{Percentage in quantity demanded}}{\text{Percentage change in price}}.$$

It's important to remember that *the price elasticity of demand is not the same as the slope of the demand curve.*

If we calculate the price elasticity of demand for a price cut, the percentage change in price will be negative, and the percentage change in quantity demanded will be positive. Similarly, if we calculate the price elasticity of demand for a price increase, the percentage change in price will be positive, and the percentage change in quantity demanded will be negative. Therefore, the price elasticity of demand is always negative. In comparing elasticities, though, we are usually interested in their relative size. So, we often drop the minus sign and compare their *absolute values*. For example, although -3 is actually a smaller number than -2 , we say that a price elasticity of -3 is larger than a price elasticity of -2 .

MyEconLab Concept Check

Elastic Demand and Inelastic Demand

If the quantity demanded is very responsive to changes in price, the percentage change in quantity demanded will be *greater* than the percentage change in price, and the price elasticity of demand will be greater than 1 in absolute value. In this case, demand is **elastic**. For example, if a 10 percent decrease in the price of bagels results in a 20 percent increase in the quantity of bagels demanded, then:

$$\text{Price elasticity of demand} = \frac{20\%}{-10\%} = -2,$$

and we can conclude that the demand for bagels is elastic.

When the quantity demanded is not very responsive to price, however, the percentage change in quantity demanded will be *less* than the percentage change in price, and the price elasticity of demand will be less than 1 in absolute value. In this case, demand is **inelastic**. For example, if a 10 percent decrease in the price of wheat results in a 5 percent increase in the quantity of wheat demanded, then:

$$\text{Price elasticity of demand} = \frac{5\%}{-10\%} = -0.5,$$

and we can conclude that the demand for wheat is inelastic.

In the special case where the percentage change in quantity demanded is equal to the percentage change in price, the price elasticity of demand equals -1 (or 1 in absolute value). In this case, demand is **unit elastic**.

MyEconLab Concept Check

An Example of Computing Price Elasticities

Suppose you own a service station, and you are trying to decide whether to cut the price you are charging for a gallon of gas. You are currently at point A in Figure 6.1, selling 1,000 gallons per day at a price of \$3.00 per gallon. How many more gallons you will sell by cutting the price to \$2.70 depends on the price elasticity of demand for gasoline

Elastic demand Demand is elastic when the percentage change in the quantity demanded is *greater* than the percentage change in price, so the price elasticity is *greater* than 1 in absolute value.

Inelastic demand Demand is inelastic when the percentage change in quantity demanded is *less* than the percentage change in price, so the price elasticity is *less* than 1 in absolute value.

Unit-elastic demand Demand is unit elastic when the percentage change in quantity demanded is *equal* to the percentage change in price, so the price elasticity is equal to 1 in absolute value.

MyEconLab Animation

Figure 6.1

Elastic and Inelastic Demand

Along D_1 , cutting the price from \$3.00 to \$2.70 increases the number of gallons demanded from 1,000 to 1,200 per day. Because the percentage change in quantity demanded is greater than the percentage change in price (in absolute value), demand is elastic between point A and point B. Along D_2 , cutting the price from \$3.00 to \$2.70 increases the number of gallons demanded only from 1,000 to 1,050 per day. Because the percentage change in quantity demanded is smaller than the percentage change in price (in absolute value), demand is inelastic between point A and point C.

at your service station. Let's consider two possibilities: If D_1 is the demand curve for gasoline at your station, your sales will increase to 1,200 gallons per day, point B. But if D_2 is your demand curve, your sales will increase only to 1,050 gallons per day, point C. We might expect—correctly, as we will see—that between these points, demand curve D_1 is *elastic* and demand curve D_2 is *inelastic*.

To confirm that D_1 is elastic between these points and that D_2 is inelastic, we need to calculate the price elasticity of demand for each curve. In calculating price elasticity between two points on a demand curve, though, we face a problem because we get a different value for price increases than for price decreases. Suppose we calculate the price elasticity for D_1 as the price is cut from \$3.00 to \$2.70. This 10 percent price cut increases the quantity demanded from 1,000 gallons to 1,200 gallons, or by 20 percent. Therefore, the price elasticity of demand between points A and B is $20\% / -10\% = -2.0$. Now let's calculate the price elasticity for D_1 as the price is *increased* from \$2.70 to \$3.00. This 11.1 percent price increase causes a decrease in the quantity demanded from 1,200 gallons to 1,000 gallons, or by 16.7 percent. So, now our measure of the price elasticity of demand between points A and B is $-16.7\% / 11.1\% = -1.5$. It can be confusing to have different values for the price elasticity of demand between the same two points on the same demand curve. As we will see in the next section, economists use a formula that allows them to avoid this confusion when calculating elasticities.

MyEconLab Concept Check

The Midpoint Formula

We can use the *midpoint formula* to ensure that we have only one value of the price elasticity of demand between the same two points on a demand curve. The midpoint formula uses the *average* of the initial and final quantities and the initial and final prices. If Q_1 and P_1 are the initial quantity and price, and Q_2 and P_2 are the final quantity and price, the midpoint formula is:

$$\text{Price elasticity of demand} = \frac{(Q_2 - Q_1)}{\left(\frac{Q_1 + Q_2}{2}\right)} \div \frac{(P_2 - P_1)}{\left(\frac{P_1 + P_2}{2}\right)}$$

The midpoint formula may seem challenging at first, but the numerator is just the change in quantity divided by the average of the initial and final quantities, and the denominator is just the change in price divided by the average of the initial and final prices.

Let's apply the formula to calculating the price elasticity of D_1 in Figure 6.1. Between point A and point B on D_1 , the change in quantity is 200, and the average of the two quantities is 1,100. Therefore, there is an 18.2 percent change in quantity demanded. The change in price is $-\$0.30$, and the average of the two prices is $\$2.85$. Therefore, there is a -10.5 percent change in price. So, the price elasticity of demand is $18.2\% / -10.5\% = -1.7$. Notice these three results from calculating the price elasticity of demand using the midpoint formula:

1. As we suspected from examining Figure 6.1, demand curve D_1 is elastic between points A and B.
2. The value for the price elasticity calculated using the midpoint formula is between the two values we calculated earlier.
3. The midpoint formula will give us the same value whether we are moving from the higher price to the lower price or from the lower price to the higher price.

We can also use the midpoint formula to calculate the elasticity of demand between point A and point C on D_2 . In this case, there is a 4.9 percent change in quantity and a -10.5 percent change in price. So, the elasticity of demand is $4.9\% / -10.5\% = -0.5$. Once again, as we suspected, demand curve D_2 is price inelastic between points A and C.

MyEconLab **Concept Check**

Solved Problem 6.1

Calculating the Price Elasticity of Demand

Suppose you own a service station, and you are currently selling gasoline for $\$2.50$ per gallon. At this price, you can sell 2,000 gallons per day. You are considering cutting the price to $\$2.30$ to attract drivers who have been buying their gas at competing stations. The following graph shows two possible increases in the quantity of gasoline sold as a

result of your price cut. Use the information in the graph to calculate the price elasticity between these two prices on each of the demand curves. Use the midpoint formula in your calculations. State whether each demand curve is elastic or inelastic between these two prices.

Solving the Problem

Step 1: Review the chapter material. This problem requires calculating the price elasticity of demand, so you may want to review the material in the section “The Midpoint Formula,” which begins on page 244.

Step 2: To begin using the midpoint formula, calculate the average quantity and the average price for demand curve D_1 .

$$\text{Average quantity} = \frac{2,000 + 2,500}{2} = 2,250$$

$$\text{Average price} = \frac{\$2.50 + \$2.30}{2} = \$2.40$$

Step 3: Now calculate the percentage change in the quantity demanded and the percentage change in price for demand curve D_1 .

$$\text{Percentage change in quantity demanded} = \frac{2,500 - 2,000}{2,250} \times 100 = 22.2\%$$

$$\text{Percentage change in price} = \frac{\$2.30 - \$2.50}{\$2.40} \times 100 = -8.3\%$$

Step 4: Divide the percentage change in the quantity demanded by the percentage change in price to arrive at the price elasticity for demand curve D_1 .

$$\text{Price elasticity of demand} = \frac{22.2\%}{-8.3\%} = -2.7$$

Because the elasticity is greater than 1 in absolute value, D_1 is price *elastic* between these two prices.

Step 5: Calculate the price elasticity of demand curve D_2 between these two prices.

$$\text{Percentage change in quantity demanded} = \frac{2,100 - 2,000}{2,050} \times 100 = 4.9\%$$

$$\text{Percentage change in price} = \frac{\$2.30 - \$2.50}{\$2.40} \times 100 = -8.3\%$$

$$\text{Price elasticity of demand} = \frac{4.9\%}{-8.3\%} = -0.6$$

Because the elasticity is less than 1 in absolute value, D_2 is price *inelastic* between these two prices.

When Demand Curves Intersect, the Flatter Curve Is More Elastic

Remember that *elasticity* is not the same thing as *slope*. While slope is calculated using changes in quantity and price, elasticity is calculated using percentage changes. But it is true that if two demand curves intersect:

- The demand curve with the smaller slope (in absolute value)—the flatter demand curve—is more elastic.
- The demand curve with the larger slope (in absolute value)—the steeper demand curve—is less elastic.

In Figure 6.1, for a given change in price, demand curve D_1 is more elastic than demand curve D_2 .

MyEconLab Concept Check

Polar Cases of Perfectly Elastic and Perfectly Inelastic Demand

Although they do not occur frequently, you should be aware of the extreme, or *polar*, cases of price elasticity. If a demand curve is a vertical line, it is **perfectly inelastic**. In this case, the quantity demanded is completely unresponsive to price, and the price elasticity of demand equals zero. No matter how much price may increase or decrease, the quantity remains the same. For only a very few products will the quantity demanded be completely unresponsive to the price, making the demand curve a vertical line. The drug insulin is an example. Some diabetics must take a certain amount of insulin each day. If the price of insulin declines, it will not affect the required dose and therefore will not increase the quantity demanded. Similarly, a price increase will not affect the required dose or decrease the quantity demanded. (Of course, some diabetics may not be able to afford insulin at a higher price. If so, even in this case the demand curve may not be completely vertical and, therefore, not perfectly inelastic.)

If a demand curve is a horizontal line, it is **perfectly elastic**. In this case, the quantity demanded is infinitely responsive to price, and the price elasticity of demand equals infinity. If a demand curve is perfectly elastic, an increase in price causes the quantity demanded to fall to zero. Once again, perfectly elastic demand curves are rare, and it is important not to confuse *elastic* with *perfectly elastic*. Table 6.1 on the next page summarizes the different price elasticities of demand.

MyEconLab **Concept Check**

Perfectly inelastic demand The case where the quantity demanded is completely unresponsive to price and the price elasticity of demand equals zero.

Perfectly elastic demand The case where the quantity demanded is infinitely responsive to price and the price elasticity of demand equals infinity.

Don't Let This Happen to You

Don't Confuse Inelastic with Perfectly Inelastic

You may be tempted to simplify the concept of elasticity by assuming that any demand curve described as being inelastic is *perfectly* inelastic. You should never make this assumption because perfectly inelastic demand curves are rare. For example, consider the following problem: "Use a demand and supply graph to show how a decrease in supply affects the equilibrium quantity of gasoline. Assume that the demand for gasoline is inelastic." The following graph would be an *incorrect* answer to this problem:

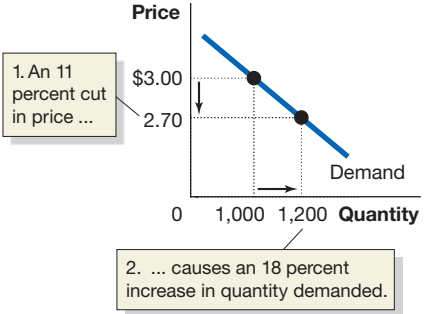

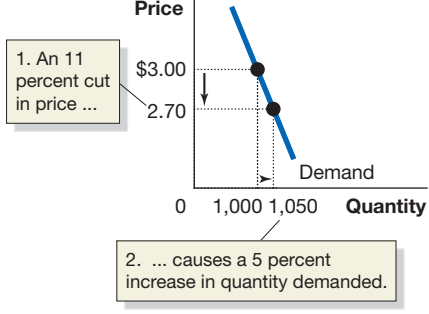

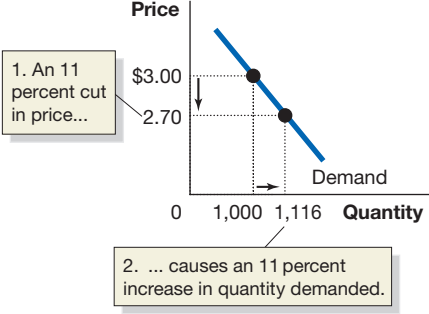

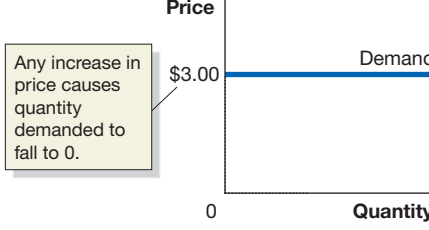

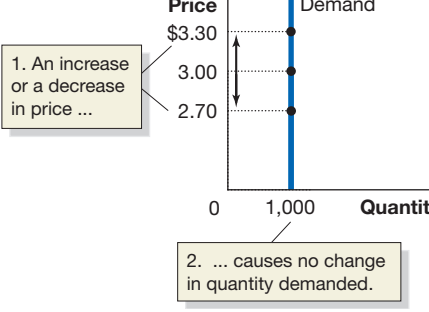

The demand for gasoline is inelastic, but it is not *perfectly* inelastic. When the price of gasoline rises, the quantity demanded falls. So, the correct answer to this problem would use a graph showing a typical downward-sloping demand curve rather than a vertical demand curve:

6.2 The Determinants of the Price Elasticity of Demand

LEARNING OBJECTIVE: List and explain the determinants of the price elasticity of demand.

We have seen that the demand for some products may be elastic, while the demand for other products may be inelastic. In this section, we examine why price elasticities differ among products. The key determinants of the price elasticity of demand are:

- The availability of close substitutes to the good
- The passage of time
- Whether the good is a luxury or a necessity
- The definition of the market
- The share of the good in the consumer's budget

Availability of Close Substitutes

How consumers react to a change in the price of a product depends on whether there are alternative products. So the availability of substitutes is the most important determinant of price elasticity of demand. For example, when the price of gasoline rises, consumers have few alternatives, so the quantity demanded falls only a little. But if the price of pizza rises, consumers have many alternative foods they can eat, so the quantity demanded is likely to fall substantially. In fact, a key constraint on a firm's pricing policies is how many close substitutes exist for its product. In general, *if a product has more substitutes available, it will have a more elastic demand. If a product has fewer substitutes available, it will have a less elastic demand.*

MyEconLab Concept Check

Passage of Time

It usually takes consumers some time to adjust their buying habits when prices change. If the price of chicken falls, for example, it takes a while before consumers decide to change from eating chicken for dinner once a week to eating it twice a week. If the price of gasoline increases, it also takes a while for consumers to decide to begin taking public transportation, to buy more fuel-efficient cars, or to find new jobs closer to where they live. *The more time that passes, the more elastic the demand for a product becomes.*

MyEconLab Concept Check

Luxuries versus Necessities

Goods that are luxuries usually have more elastic demand curves than goods that are necessities. For example, the demand for bread is inelastic because bread is a necessity, and the quantity that people buy is not very dependent on its price. Tickets to a concert are a luxury, so the demand for concert tickets is much more elastic than the demand for bread. *The demand curve for a luxury is more elastic than the demand curve for a necessity.*

MyEconLab Concept Check

Definition of the Market

In a narrowly defined market, consumers have more substitutes available. For example, if you own a service station and raise the price you charge for gasoline, many of your customers will switch to buying from a competitor. So, the demand for gasoline at one particular station is likely to be elastic. The demand for gasoline as a product, on the other hand, is inelastic because consumers have few alternatives (in the short run) to buying it. *The more narrowly we define a market, the more elastic demand will be.*

MyEconLab Concept Check

Share of a Good in a Consumer's Budget

Goods that take only a small fraction of a consumer's budget tend to have less elastic demand than goods that take a large fraction. For example, most people buy table salt infrequently and in relatively small quantities. The share of an average consumer's budget that is spent on salt is very low. As a result, even a doubling of the price of salt is likely to result in only a small decline in the quantity of salt demanded. "Big-ticket items," such as houses, cars, and furniture, take up a larger share in the average consumer's budget. Increases in the prices of these goods are likely to result in significant declines in the quantity demanded. In general, *the demand for a good will be more elastic the larger the share of the good in the average consumer's budget.*

MyEconLab **Concept Check**

Some Estimated Price Elasticities of Demand

Table 6.2 shows some estimated short-run price elasticities of demand. It's important to remember that estimates of the price elasticities of different goods can vary, depending on the data used and the time period over which the estimates were made. The results given in the table are consistent with our discussion of the determinants of price elasticity. Goods for which there are few substitutes, such as cigarettes, gasoline, and health insurance, are price inelastic, as are broadly defined goods, such as bread and beer. Particular brands of products such as Coca-Cola, Tide, and Post Raisin Bran are price elastic.

Table 6.2 also shows that:

- The demand for books or DVDs bought from a particular retailer is typically price elastic. Note, though, that the demand for books from Amazon is inelastic, which indicates that consumers do not consider ordering from other online sites to be good substitutes for ordering from Amazon.
- An increase in the price of grapes will lead some consumers to substitute other fruits, so demand for grapes is price elastic.
- Similarly, an increase in the price of new automobiles will lead some consumers to buy used automobiles or to continue driving their current cars, so demand for automobiles is also price elastic.
- The demand for necessities, such as natural gas and water, is price inelastic.

6.3 The Relationship between Price Elasticity of Demand and Total Revenue

LEARNING OBJECTIVE: Explain the relationship between the price elasticity of demand and total revenue.

Knowing the price elasticity of demand allows a firm to calculate how changes in price will affect its **total revenue**, which is the total amount of funds it receives from selling a good or service. Total revenue is calculated by multiplying price per unit by the number of units sold:

- When demand is inelastic, price and total revenue move in the same direction: An increase in price raises total revenue, and a decrease in price reduces total revenue.
- When demand is elastic, price and total revenue move inversely: An increase in price reduces total revenue, and a decrease in price raises total revenue.

To understand the relationship between price elasticity and total revenue, consider Figure 6.2. Panel (a) shows a demand curve for gasoline that is inelastic between point A and point B. (It was demand curve D_2 in Figure 6.1 on page 244.) The total revenue received by the service station owner at point A equals the price of \$3.00 multiplied by the 1,000 gallons sold, or \$3,000. This amount equals the areas of rectangles C and D in the figure because together the rectangles have a height of \$3.00 and a base of 1,000 gallons. Because this demand curve is inelastic between point A and point B, cutting the price to \$2.70 (point B) reduces total revenue. The new total revenue is shown by the areas of rectangles D and E and is equal to \$2.70 multiplied by 1,050 gallons, or \$2,835. Total revenue falls because the increase in the quantity demanded is not large enough to make up for the decrease in price. As a result, the \$135 increase in revenue gained as a result of the price cut—rectangle E—is less than the \$300 in revenue lost—rectangle C.

Total revenue The total amount of funds a seller receives from selling a good or service, calculated by multiplying price per unit by the number of units sold.

MyEconLab Animation

Figure 6.2 The Relationship between Price Elasticity and Total Revenue

When demand is inelastic, a cut in price will decrease total revenue. In panel (a), at point A, the price is \$3.00, 1,000 gallons are sold, and total revenue received by the service station equals $\$3.00 \times 1,000$ gallons, or \$3,000. At point B, cutting the price to \$2.70 increases the quantity demanded to 1,050 gallons, but the fall in price more than offsets the increase in quantity. As a result, revenue falls to $\$2.70 \times 1,050$ gallons, or \$2,835. When demand

is elastic, a cut in the price will increase total revenue. In panel (b), at point A, the areas of rectangles C and D are still equal to \$3,000. But at point B, the areas of rectangles D and E are equal to $\$2.70 \times 1,200$ gallons, or \$3,240. In this case, the increase in the quantity demanded is large enough to offset the fall in price, so total revenue increases.

Table 6.3
The Relationship between Price Elasticity and Revenue

If demand is ...	then ...	because ...
elastic	an increase in price reduces revenue	the decrease in quantity demanded is proportionally <i>greater</i> than the increase in price.
elastic	a decrease in price increases revenue	the increase in quantity demanded is proportionally <i>greater</i> than the decrease in price.
inelastic	an increase in price increases revenue	the decrease in quantity demanded is proportionally <i>smaller</i> than the increase in price.
inelastic	a decrease in price reduces revenue	the increase in quantity demanded is proportionally <i>smaller</i> than the decrease in price.
unit elastic	an increase in price does not affect revenue	the decrease in quantity demanded is proportionally <i>the same</i> as the increase in price.
unit elastic	a decrease in price does not affect revenue	the increase in quantity demanded is proportionally <i>the same</i> as the decrease in price.

Panel (b) of Figure 6.2 shows a demand curve that is elastic between point A and point B. (It was demand curve D_1 in Figure 6.1.) With this demand curve, cutting the price increases total revenue. At point A, the areas of rectangles C and D are still equal to \$3,000, but at point B, the areas of rectangles D and E are equal to \$2.70 multiplied by 1,200 gallons, or \$3,240. Here, total revenue rises because the increase in the quantity demanded is large enough to offset the lower price. As a result, the \$540 increase in revenue gained as a result of the price cut—rectangle E—is greater than the \$300 in revenue lost—rectangle C.

A less common possibility than those shown in Figure 6.2 is that demand is unit elastic. In that case, a small change in price is exactly offset by a proportional change in the quantity demanded, leaving revenue unaffected. Therefore, when demand is unit elastic, neither a decrease nor an increase in price affects revenue. Table 6.3 summarizes the relationship between price elasticity and revenue.

Elasticity and Revenue with a Linear Demand Curve

Along most demand curves, elasticity is not constant at every point. For example, a straight-line, or linear, demand curve for gasoline is shown in panel (a) of Figure 6.3. (For simplicity, small quantities are used.) The numbers from the table are plotted in the graphs. The demand curve shows that when the price drops by \$1 per gallon, consumers always respond by buying 2 more gallons per day. When the price is high and the quantity demanded is low, demand is elastic. Demand is elastic because a \$1 drop in price is a smaller percentage change when the price is high, and an increase of 2 gallons is a larger percentage change when the quantity of gasoline purchased is low. By similar reasoning, we can see why demand is inelastic when the price is low and the quantity demanded is high.

Panel (a) in Figure 6.3 shows that when price is between \$8 and \$4 and quantity demanded is between 0 gallons and 8 gallons, demand is elastic. Panel (b) shows that over this same range, total revenue will increase as price falls. For example, in panel (a), as price falls from \$7 to \$6, the quantity demanded increases from 2 to 4, and in panel (b), total revenue increases from \$14 to \$24. Similarly, when price is between \$4 and \$0 and the quantity demanded is between 8 and 16, demand is inelastic. Over this same range, total revenue will decrease as price falls. For example, as price falls from \$3 to \$2 and the quantity demanded increases from 10 to 12, total revenue decreases from \$30 to \$24.

MyEconLab Animation

Figure 6.3 Elasticity Is Not Constant along a Linear Demand Curve

The data from the table are plotted in the graphs. Panel (a) shows that as we move down the demand curve for gasoline, the price elasticity of demand declines. In other words, at higher prices, demand is elastic, and at lower prices, demand is inelastic. Panel (b) shows that as the quantity of gasoline

purchased increases from 0, revenue will increase until it reaches a maximum of \$32 when 8 gallons are purchased. As purchases increase beyond 8 gallons, revenue falls because demand is inelastic on this portion of the demand curve.

Solved Problem 6.3

Price and Revenue Don't Always Move in the Same Direction

New York City officials believed they needed more revenue to maintain 35 city-owned recreation centers. To raise the additional revenue, the city's parks department increased the annual membership fee to use the centers from \$75 to \$150. According to an article in the *New York Times*, "the department had hoped to realize \$4 million in new revenue, but in fact, it lost about \$200,000." The article also explains that the parks department had expected a 5 percent decline in memberships due to the price increase.

- What did the parks department believe about the price elasticity of demand for memberships in its recreation centers?
- Is demand for memberships actually elastic or inelastic? Briefly explain. Illustrate your answer with a graph showing the demand curve for memberships as the parks department believed it to be and as it actually is.

Solving the Problem

- Step 1: Review the chapter material.** This problem deals with the effect of a price change on a firm's revenue, so you may want to review the section "The Relationship between Price Elasticity of Demand and Total Revenue," which begins on page 251.
- Step 2: Answer part (a) by explaining how the parks department viewed the demand for memberships.** Looking at Table 6.3, we can conclude that managers at the parks department must have thought the demand for memberships was inelastic because they believed that revenue would increase if they raised the price. The managers estimated that the quantity of memberships demanded would fall by 5 percent following the 100 percent price increase. Therefore, they must have believed that the price elasticity of demand for memberships was $-5\% / 100\% = -0.05$.
- Step 3: Answer part (b) by explaining whether the demand for memberships is actually elastic or inelastic and by drawing a graph to illustrate your answer.** Because revenue fell when the parks department raised the price, we know that demand for memberships must be elastic. In the following graph, D_1 shows the demand for memberships as the parks department believed it to be. Moving along this demand curve from point A to point B, an increase in the price from \$75 to \$150 causes a decline of only Q_1 to Q_2 in the quantity of memberships demanded. D_2 shows the demand curve as it actually is. Moving along this demand curve from point A to point C, the increase in price causes a much larger decline of Q_1 to Q_3 in memberships demanded.

Why Does Amazon Care about Price Elasticity?

In 2014, Amazon was in a dispute with a large book publisher called Hachette whose authors include James Patterson, J.K. Rowling, and J.D. Salinger. Hachette was charging between \$14.99 and \$19.99 for its e-books, but Amazon wanted the publisher to lower the price to only \$9.99. Amazon's tactics included reducing discounts on Hachette's hardcover

books, not allowing preorders of the publisher's books, and delaying shipping some of its books by two to three weeks.

But why did Amazon want Hachette to lower the price of e-books? In a posting on its Web site, Amazon asserted, "We've quantified the price elasticity of e-books from repeated measurements across many titles." Amazon estimated that the price elasticity of demand for e-books is -1.74 . The following table uses Amazon's estimate to show how sales revenue would change in response to a decrease in the price of e-books.

Price of Book	Copies Sold at That Price	Total Revenue at That Price
\$14.99	100,000	\$1,499,000
\$9.99	174,000	\$1,738,260

Amazon concluded, "At \$9.99, even though the customer is paying less, the total pie is bigger and there is more to share amongst [Amazon, Hachette, and the author of the book]."

If Amazon's analysis is correct, why would Hachette resist cutting the prices of e-books? Hachette believed that while the demand for bestsellers by authors such as James Patterson and J.K. Rowling might be price elastic, the demand for other e-books it published by less-well-known authors or on obscure subjects was price inelastic. For those books, cutting the price would reduce Hachette's revenue. In addition, Hachette believed that lower prices on e-books might come at the expense of sales of hardcover copies of those books, on which the publisher made higher profits. Eventually, Amazon and Hachette reached an agreement that allowed Hachette to determine the prices its e-books would sell for on Amazon's site.

With a relatively new product, such as e-books, businesses often have to experiment with different prices as they attempt to determine the price elasticity of demand. Knowing the price elasticity is important to a business in determining the price that will maximize profit.

6.4 Other Demand Elasticities

LEARNING OBJECTIVE: Define cross-price elasticity of demand and income elasticity of demand and understand their determinants and how they are measured.

Elasticity is an important concept in economics because it allows us to quantify the responsiveness of one economic variable to changes in another economic variable. In addition to price elasticity, two other demand elasticities are important:

1. Cross-price elasticity of demand
2. Income elasticity of demand

Cross-Price Elasticity of Demand

Suppose you work at Apple, and you need to predict the effect of an increase in the price of Samsung's Galaxy Gear smartwatch on the quantity of Apple Watches demanded, holding other factors constant. You can do this by calculating the **cross-price elasticity of demand**, which is the percentage change in the quantity of Apple

Cross-price elasticity of demand The percentage change in the quantity demanded of one good divided by the percentage change in the price of another good.

Watches demanded divided by the percentage change in the price of Galaxy Gears—or, in general:

$$\text{Cross-price elasticity of demand} = \frac{\text{Percentage change in quantity demanded of one good}}{\text{Percentage change in price of another good}}$$

The cross-price elasticity of demand is positive or negative, depending on whether the two products are substitutes or complements. Recall that substitutes are products that can be used for the same purpose, such as two brands of smartwatches. Complements are products that are used together, such as smartwatches and applications that can be downloaded from online stores. An increase in the price of a substitute will lead to an increase in the quantity demanded, so the cross-price elasticity of demand will be positive. An increase in the price of a complement will lead to a decrease in the quantity demanded, so the cross-price elasticity of demand will be negative. Of course, if the two products are unrelated—such as smartwatches and peanut butter—the cross-price elasticity of demand will be zero. Table 6.4 summarizes the key points about the cross-price elasticity of demand.

Cross-price elasticity of demand is important to firm managers because it allows them to measure whether products sold by other firms are close substitutes for their products. For example, Pepsi-Cola and Coca-Cola both spend heavily on advertising, each hoping to convince consumers that its cola tastes better than its rival's. How can these firms tell whether their advertising campaigns have been effective? One way is by seeing whether the cross-price elasticity of demand has changed. If, for instance, Coca-Cola has a successful advertising campaign, when it increases the price of Coke, the percentage increase in sales of Pepsi should be smaller. In other words, the value of the cross-price elasticity of demand should have declined.

Income Elasticity of Demand

Income elasticity of demand A measure of the responsiveness of the quantity demanded to changes in income, measured by the percentage change in the quantity demanded divided by the percentage change in income.

The **income elasticity of demand** measures the responsiveness of the quantity demanded to changes in income. It is calculated as follows:

$$\text{Income elasticity of demand} = \frac{\text{Percentage change in quantity demanded}}{\text{Percentage change in income}}$$

We know that if the quantity demanded of a good increases as income increases, then the good is a *normal good* (see Chapter 3). Normal goods are often further subdivided into *luxuries* and *necessities*. A good is a luxury if the quantity demanded is very responsive to changes in income so that a 10 percent increase in income results in more than a 10 percent increase in the quantity demanded. Expensive jewelry and vacation homes are examples of luxuries. A good is a necessity if the quantity demanded is not very responsive to changes in income so that a 10 percent increase in income results in less than a 10 percent increase in the quantity demanded. Food and clothing are examples of necessities. A good is *inferior* if the quantity demanded falls when income increases. Ground beef with a high fat content is an example of an inferior good. We should note that *normal good*, *inferior good*, *necessity*, and *luxury* are just labels economists use for goods with different income elasticities; the labels are not intended to be value judgments about the worth of these goods.

If the income elasticity of demand is ...	then the good is ...	Example
positive but less than 1	normal and a necessity.	Bread
positive and greater than 1	normal and a luxury.	Caviar
negative	inferior.	High-fat meat

Table 6.5

Summary of Income Elasticity of Demand

Because most goods are normal goods, during periods of economic expansion when consumer income is rising, most firms can expect—holding other factors constant—that the quantity demanded of their products will increase. Sellers of luxuries can expect particularly large increases. During recessions, falling consumer income can cause firms to experience increases in demand for inferior goods. For example, the demand for bus trips increases as consumers cut back on air travel, and supermarkets find that the demand for canned tuna increases relative to the demand for fresh salmon. Table 6.5 summarizes the key points about the income elasticity of demand.

Price Elasticity, Cross-Price Elasticity, and Income Elasticity in the Market for Alcoholic Beverages

Many public policy issues are related to the consumption of alcoholic beverages. These issues include underage drinking, drunk driving, and the possible beneficial effects of red wine in lowering the risk of heart disease. Knowing how responsive the demand for alcohol is to changes in price provides insight into these policy issues. Christopher Ruhm of the University of Virginia and colleagues have estimated statistically the following elasticities. (*Spirits* refers to all beverages, other than beer and wine, that contain alcohol.)

Price elasticity of demand for beer	−0.30
Cross-price elasticity of demand between beer and wine	−0.83
Cross-price elasticity of demand between beer and spirits	−0.50
Income elasticity of demand for beer	0.09

These results indicate that the demand for beer is inelastic. A 10 percent increase in the price of beer will result in a 3 percent decline in the quantity of beer demanded. Somewhat surprisingly, both wine and spirits are complements for beer rather than substitutes. A 10 percent increase in the price of wine will result in an 8.3 percent *decrease* in the quantity of beer demanded. Previous studies of the price elasticity of beer had found that beer was a substitute for other alcoholic drinks. Ruhm and his colleagues argue that their results are more reliable because they use Uniform Product Code (UPC) scanner data on prices and quantities sold in grocery stores. They argue that these price data are more accurate than the data used in many previous studies that included the prices of only one brand each of beer, wine, and whiskey.

The results in the table also show that a 10 percent increase in income will result in a 0.9 percent *increase* in the quantity of beer demanded. So, beer is a normal good. According to the definitions given earlier, beer would be classified as a necessity because it has an income elasticity that is positive but less than 1.

6.5 Using Elasticity to Analyze the Disappearing Family Farm

LEARNING OBJECTIVE: Use price elasticity and income elasticity to analyze economic issues.

The concepts of price elasticity and income elasticity can help us understand many economic issues. For example, some people are concerned that the family farm is becoming an endangered species in the United States. Although food production has been growing steadily, the number of farms and farmers continue to dwindle. In 1950, the United States had more than 5 million farms, and more than 23 million people lived on farms. By 2015, only about 2 million farms remained, and fewer than 3 million people lived on them. The federal government has several programs that are intended to aid farmers (see Chapter 4). Many of these programs have been aimed at helping small, family-operated farms, but growth in farm production, combined with low price and income elasticities for most food products, have made it difficult for owners of family farms to earn a profit.

Productivity measures the ability of firms to produce goods and services with a given amount of economic inputs, such as workers, machines, and land. Productivity has grown very rapidly in U.S. agriculture. In 1950, the average U.S. wheat farmer harvested about 17 bushels from each acre of wheat planted. By 2015, because of the development of superior strains of wheat and improvements in farming techniques, the average American wheat farmer harvested 44 bushels per acre. So, even though the total number of acres devoted to growing wheat declined from about 62 million to about 48 million, total wheat production rose from about 1.0 billion bushels to about 2.1 billion.

Unfortunately for U.S. farmers, this increase in wheat production resulted in a substantial decline in wheat prices. Two key factors explain this decline: (1) The demand for wheat is inelastic, and (2) the income elasticity of demand for wheat is low. Even though the U.S. population has increased greatly since 1950 and the income of the average American is much higher than it was in 1950, the demand for wheat has increased only moderately. For all of the additional wheat to be sold, the price has had to decline. Because the demand for wheat is inelastic, the price decline has been substantial. Figure 6.4 illustrates these points.

A large shift in supply, a small shift in demand, and an inelastic demand curve combined to drive down the price of wheat from \$19.53 per bushel in 1950 to \$5.00 in

MyEconLab Animation

Figure 6.4

Elasticity and the Disappearing Family Farm

In 1950, U.S. farmers produced 1.0 billion bushels of wheat at a price of \$19.53 per bushel. Over the next 65 years, rapid increases in farm productivity caused a large shift to the right in the supply curve for wheat. The income elasticity of demand for wheat is low, so the demand for wheat increased relatively little over this period. Because the demand for wheat is also inelastic, the large shift in the supply curve and the small shift in the demand curve resulted in a sharp decline in the price of wheat, from \$19.53 per bushel in 1950 to \$5.00 in 2015.

2015. (We measure the price in 1950 in terms of prices in 2015, to adjust for the general increase in prices since 1950.) With low prices, only the most efficiently run farms have been able to remain profitable. Small family-run farms have found it difficult to survive, and many of these farms have disappeared. The markets for most other food products are similar to the market for wheat. They are characterized by output growth and low income and price elasticities. The result is the paradox of U.S. farming: ever more abundant and cheaper food, supplied by fewer and fewer farms. U.S. consumers have benefited, but most family farmers have not.

Solved Problem 6.5

MyEconLab Interactive Animation

Using Price Elasticity to Analyze a Policy of Taxing Gasoline

If the consumption of a product results in a negative externality, taxing the product may improve economic efficiency (see Chapter 5). Some economists and policymakers argue that driving cars and trucks causes an externality because they: (1) burn gasoline, which increases emissions of greenhouse gases; (2) contribute to the congestion that clogs many highways in and around big cities; and (3) cause accidents that take more than 30,000 lives per year. Some economists have suggested substantially increasing the federal excise tax on gasoline, which in 2015 was 18.4 cents per gallon. How much the tax would cause consumption to fall and how much revenue the tax would raise depend on the price elasticity of demand. Suppose that the price of gasoline is currently \$3.00 per gallon, the quantity of gasoline demanded is 140 billion gallons per

year, the price elasticity of demand for gasoline is -0.06 , and the federal government decides to increase the excise tax on gasoline by \$1.00 per gallon. The price of a product will not rise by the full amount of a tax increase unless the demand for the product is perfectly inelastic (see Chapter 4). In this case, suppose that the price of gasoline increases by \$0.80 per gallon after the \$1.00 excise tax is imposed.

- What is the new quantity of gasoline demanded after the tax is imposed? How effective would a gas tax be in reducing consumption of gasoline in the short run?
- How much revenue does the federal government receive from the tax?

Solving the Problem

Step 1: Review the chapter material. This problem deals with applications of the price elasticity of demand formula, so you may want to review the section “Measuring the Price Elasticity of Demand,” which begins on page 242.

Step 2: Answer the first question in part (a) using the formula for the price elasticity of demand to calculate the new quantity demanded.

$$\text{Price elasticity of demand} = \frac{\text{Percentage change in quantity demanded}}{\text{Percentage change in price}}$$

We can plug into the midpoint formula the values given for the price elasticity, the original price of \$3.00, and the new price of \$3.80 ($= \$3.00 + \0.80).

$$-0.06 = \frac{\text{Percentage change in quantity demanded}}{\frac{(\$3.80 - \$3.00)}{\left(\frac{\$3.00 + \$3.80}{2}\right)}}$$

Or, rearranging and writing out the expression for the percentage change in the quantity demanded:

$$-0.014 = \frac{(Q_2 - 140 \text{ billion})}{\left(\frac{140 \text{ billion} + Q_2}{2}\right)}$$

Solving for Q_2 , the new quantity demanded is:

$$Q_2 = 138.1 \text{ billion gallons.}$$

Step 3: Answer the second question in part (a). Because the price elasticity of demand for gasoline is only -0.06 , even a substantial increase in the gasoline tax of \$1.00 per gallon would reduce gasoline consumption by only a small amount: from 140 billion gallons of gasoline per year to 138.1 billion gallons. Note, though, that price elasticities typically increase over time. Economists estimate that the long-run price elasticity of gasoline is in the range of -0.40 to -0.60 , so in the long run, the decline in the consumption of gasoline would be larger.

Step 4: Calculate the revenue earned by the federal government to answer part (b). The federal government would collect an amount equal to the tax per gallon multiplied by the number of gallons sold: \$1 per gallon \times 138.1 billion gallons = \$138.1 billion.

Extra Credit: The tax of \$138.1 billion calculated in step 4 is substantial: It is equivalent to about 10 percent of all the revenue the federal government raised from the personal income tax in 2014. It is also much larger than the roughly \$25 billion the federal government receives each year from the existing 18.4-cents-per-gallon gasoline tax. We can conclude that raising the federal excise tax on gasoline would be a good way to raise revenue for the federal government. But, at least in the short run, increasing the tax would not greatly reduce the quantity of gasoline consumed. Notice that if the demand for gasoline were elastic, this result would be reversed: The quantity of gasoline consumed would decline much more, but so would the revenue that the federal government would receive from the tax increase.

6.6

The Price Elasticity of Supply and Its Measurement

LEARNING OBJECTIVE: Define price elasticity of supply and understand its determinants and how it is measured.

We can use the concept of elasticity to measure the responsiveness of firms to a change in price, just as we used it to measure the responsiveness of consumers. We know from the law of supply that when the price of a product increases, the quantity supplied increases. To measure how much the quantity supplied increases when price increases, we use the *price elasticity of supply*.

Measuring the Price Elasticity of Supply

As we did with the price elasticity of demand, we calculate the **price elasticity of supply** by using percentage changes:

$$\text{Price elasticity of supply} = \frac{\text{Percentage change in quantity supplied}}{\text{Percentage change in price}}$$

Notice that because supply curves are upward sloping, the price elasticity of supply will be a positive number. We categorize the price elasticity of supply the same way we categorized the price elasticity of demand:

- If the price elasticity of supply is less than 1, then supply is *inelastic*. For example, economists have estimated that over a period of a year, the price elasticity of supply of gasoline from U.S. oil refineries is about 0.20. So, gasoline supply is inelastic: A 10 percent increase in the price of gasoline will result in only a 2 percent increase in the quantity supplied.
- If the price elasticity of supply is greater than 1, then supply is *elastic*. For example, if the price of wheat increases by 10 percent and the quantity of wheat that farmers supply increases by 15 percent, the price elasticity of supply is 1.5. So wheat supply is elastic.
- If the price elasticity of supply is equal to 1, the supply is *unit elastic*. For example, if the price of bottled water increases by 10 percent and the quantity of bottled

Price elasticity of supply The responsiveness of the quantity supplied to a change in price, measured by dividing the percentage change in the quantity supplied of a product by the percentage change in the product's price.

water that firms supply increases by 10 percent, the price elasticity of supply equals 1. So bottled water supply is unit elastic.

As with other elasticity calculations, when we calculate the price elasticity of supply, we hold constant the values of other variables.

MyEconLab Concept Check

Determinants of the Price Elasticity of Supply

Whether supply is elastic or inelastic depends on the ability and willingness of firms to alter the quantity they produce as price increases. Often, firms have difficulty increasing the quantity of the product they supply during any short period of time. For example, a pizza parlor cannot produce more pizzas on any one night than is possible using the ingredients in the kitchen. Within a day or two, it can buy more ingredients, and within a few months, it can hire more cooks and install additional ovens. As a result, the supply curve for pizza and most other products will be inelastic if we measure it over a short period of time, but the supply curve will be increasingly elastic the longer the period of time over which we measure it. Products that require resources that are themselves in fixed supply are an exception to this rule. For example, a French winery may rely on a particular variety of grape. If all the land on which that grape can be grown is already planted in vineyards, then the supply of that wine will be inelastic even over a long period.

Why Are Oil Prices So Unstable?

Bringing oil to market is a long process. Oil companies hire geologists to locate fields for exploratory oil well drilling. If significant amounts of oil are present, the company begins full-scale development of the field. From exploration to pumping significant amounts of oil can take years. This long process is the reason for the low short-run price elasticity of supply for oil. Because there are no close substitutes for oil, the short-run price elasticity of demand for oil is also low.

As the world economy recovered from the effects of the deep recession of 2007–2009, the demand for oil increased rapidly in a number of countries, particularly China, India, Russia, and Brazil. As the following graph shows, when supply is inelastic, an increase in demand can cause a large increase in price. The shift in the demand curve from D_1 to D_2 causes the equilibrium quantity of oil to increase by less than 5 percent, from 85 million barrels per day in 2009 to 89 million in 2011, but the equilibrium price to increase 175 percent, from \$40 to \$110 per barrel.

Since the 1970s, the world oil market has been heavily influenced by the Organization of the Petroleum Exporting Countries (OPEC). OPEC has 11 members, including Saudi Arabia, Kuwait, Iran, Venezuela, and Nigeria. Together, OPEC members own 75 percent

of the world's proven oil reserves. In recent years, though, production of oil in the United States has increased rapidly as a result of widespread adoption of a new technology called hydraulic fracturing, or *fracking*. Fracking involves injecting a mixture of water, sand, and chemicals into a rock formation at high pressure to release oil and natural gas that could not have been recovered using traditional methods. Largely due to fracking, oil production in the United States rose from 5.6 million barrels per day in 2011 to 8.7 million in 2014.

As the following graph shows, this expansion in U.S. production combined with greater production from some OPEC member countries caused a significant increase in the world supply of oil. (Production in some other regions, such as the North Sea, has been declining.) The price of oil declined from \$110 in 2011 to \$47 in early 2015. The extent of the price change reflected not only the size of the increase in supply but also the low short-run price elasticity of demand for oil.

The combination of a low price elasticity of demand and a low price elasticity of supply means that even relatively small increases or decreases in the demand or supply of oil can result in large swings in its equilibrium price. Over the past 40 years, the price has been as low as \$10 per barrel and as high as \$140. These price swings are likely to continue in the future.

Polar Cases of Perfectly Elastic and Perfectly Inelastic Supply

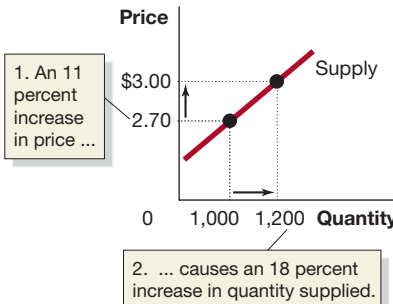

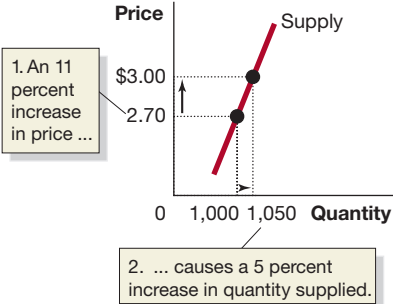

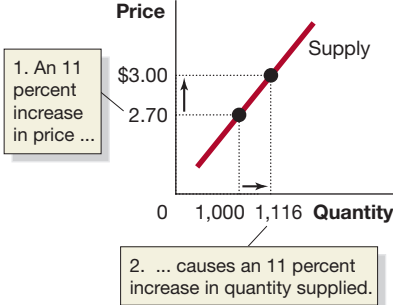

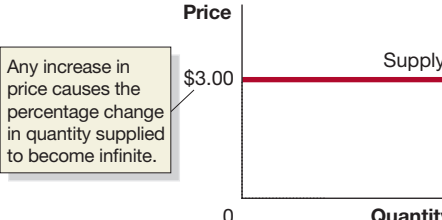

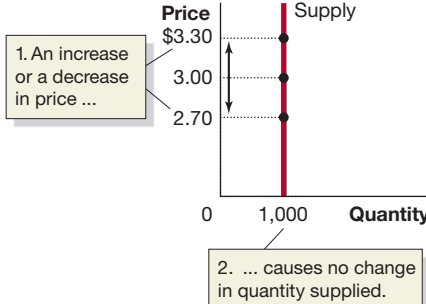

Although it occurs infrequently, supply can fall into one of the polar cases of price elasticity. If a supply curve is a vertical line, it is *perfectly inelastic*. In this case, the quantity supplied is completely unresponsive to price, and the price elasticity of supply equals zero. Regardless of how much price may increase or decrease, the quantity remains the same. Over a brief period of time, the supply of some goods and services may be perfectly inelastic. For example, a parking lot may have only a fixed number of parking spaces. If demand increases, the price to park in the lot may rise, but no more spaces will become available. Of course, if demand increases permanently, over a longer period of time, the owner of the lot may buy more land and add additional spaces.

If a supply curve is a horizontal line, it is *perfectly elastic*. In this case, the quantity supplied is infinitely responsive to price, and the price elasticity of supply equals infinity. If a supply curve is perfectly elastic, a very small increase in price causes a very large increase in the quantity supplied. Just as with demand curves, it is important not to confuse a supply curve being elastic with its being perfectly elastic and not to confuse a supply curve being inelastic with its being perfectly inelastic. Table 6.6 summarizes the different price elasticities of supply.

Using Price Elasticity of Supply to Predict Changes in Price

Figure 6.5 illustrates the important point that when demand increases, the amount by which price increases depends on the price elasticity of supply. The figure shows the demand and supply for parking spaces at a beach resort. In panel (a), on a typical summer weekend, equilibrium occurs at point A, where Demand_{Typical} intersects a supply curve that is inelastic. The increase in demand for parking spaces on July 4 shifts the demand curve to the right, moving the equilibrium to point B. Because the resort has only a limited amount of vacant land that it can use for parking, the supply curve is inelastic and the increase in demand results in a large increase in price—from \$2.00 per hour to \$4.00—but only a small increase in the quantity of spaces supplied—from 1,200 to 1,400.

In panel (b), we assume that the resort has a lot of vacant land that it can use for parking during periods of high demand, so supply is elastic. As a result, the change in equilibrium from point A to point B results in a smaller increase in price and a larger increase in the quantity supplied. An increase in price from \$2.00 per hour to \$2.50 is sufficient to increase the quantity of parking spaces supplied from 1,200 to 2,100. Knowing the price elasticity of supply makes it possible to predict more accurately how much price will change following an increase or a decrease in demand.

Economics in Your Life

How Much Do Gas Prices Matter to You?

At the beginning of the chapter, we asked you to think about three questions: What factors would make you more or less responsive to price when purchasing gasoline? Have you responded differently to price changes during different periods of your life? and Why do consumers seem to respond more to changes in gas prices at a particular service station but seem less sensitive when gas prices rise or fall at all service stations?

A number of factors are likely to affect your sensitivity to changes in gas prices, including: (1) how high your income is (and, therefore, how large a share of your budget is taken up by gasoline purchases), (2) whether you live in an area with good public transportation (which can be a substitute for having to use your own car), and (3) whether you live within walking distance of your school or job. Each of these factors may change over the course of your life, making you more or less sensitive to changes in gas prices. Finally, consumers respond to changes in the price of gas at a particular service station because gas at other service stations is a good substitute. But there are presently few good substitutes for gasoline as a product, so consumers respond much less to changes in prices at all service stations.

Conclusion

In this chapter, we have explored the important concept of elasticity. Table 6.7 summarizes the various elasticities we discussed. Computing elasticities is important in economics because it allows us to measure how one variable changes in response to changes in another variable. For example, by calculating the price elasticity of demand for its product, a firm can make a quantitative estimate of the effect of a price change on the revenue it receives. Similarly, by calculating the price elasticity of demand for cigarettes, the government can better estimate the effect of an increase in cigarette taxes on smoking.

Before going further in analyzing how firms decide on the prices to charge and the quantities to produce, we need to look at how firms are organized. We discuss this topic in the next chapter.

LEARNING OBJECTIVE: Define *price elasticity of demand* and understand how to measure it.

Summary

Elasticity measures how much one economic variable responds to changes in another economic variable. The **price elasticity of demand** measures how responsive the quantity demanded is to changes in price. The price elasticity of demand is equal to the percentage change in the quantity demanded divided by the percentage change in price. If the quantity demanded changes more than proportionally when price changes, the price elasticity of demand is greater than 1 in absolute value, and demand is **elastic**. If the quantity demanded changes less than proportionally when price changes, the price elasticity of demand is less than 1 in absolute value, and demand is **inelastic**. If the quantity demanded changes proportionally when price changes, the price elasticity of demand is equal to 1 in absolute value, and demand is **unit elastic**. **Perfectly inelastic demand** curves are vertical lines, and **perfectly elastic demand** curves are horizontal lines. Relatively few products have perfectly elastic or perfectly inelastic demand curves.

Assuming that the demand curve for places in the freshman class at Pace did not shift between 2005 and 2006, calculate the price elasticity of demand. Use the midpoint formula in your calculation. Is the demand for places in Pace's freshman class elastic or inelastic? Did the

total amount of tuition Pace received from its freshman class rise or fall in 2006 compared with 2005?

- 1.9** In 1916, the Ford Motor Company sold 500,000 Model T Fords at a price of \$440 each. Henry Ford believed that he could increase sales of the Model T by 1,000 cars for every dollar he cut the price. Use this information to calculate the price elasticity of demand for Model T Fords. - 1.10 (Related to the Don't Let This Happen to You on page 247)** The publisher of a magazine gives his staff the following information:

Current price	\$2.00 per issue
Current sales	150,000 copies per month
Current total costs	\$450,000 per month

The publisher tells the staff, "Our costs are currently \$150,000 more than our revenues each month. I propose to eliminate this problem by raising the price of the magazine to \$3.00 per issue. This will result in our revenue being exactly equal to our cost." Do you agree with the publisher's analysis? Explain. (*Hint:* Remember that a firm's revenue is calculated by multiplying the price of the product by the quantity sold.)

The Determinants of the Price Elasticity of Demand, pages 249–250

LEARNING OBJECTIVE: List and explain the determinants of the price elasticity of demand.

Summary

The main determinants of the price elasticity of demand for a good are the availability of close substitutes, the passage of time, whether the good is a necessity or a luxury, how narrowly the market for the good is defined, and the share of the good in the consumer's budget.

- 2.1** What are the key determinants of the price elasticity of demand for a product? Which determinant is the most important?
- 2.2** Is the demand for most agricultural products elastic or inelastic? Briefly explain.

Problems and Applications

- 2.3** Briefly explain the effect of the following events on price elasticity of milk:
- Soymilk becomes common in shops
 - Doctors say milk consumption is good
 - Tickets for a rock concert are immediately available
 - Goat milk becomes harder to find
- 2.4 (Related to Making the Connection on page 254)** According to the estimates of price elasticities of demand reported in Table 6.2, goods like cigarettes and cocaine

have extremely low price elasticities. On the other hand, the price elasticity for books and DVDs is very high (in absolute values). Briefly state your reasons for the occurrence of such differences.

- 2.5** One study found that the price elasticity of demand for soda is -0.78 , while the price elasticity of demand for Coca-Cola is -1.22 . Coca-Cola is a type of soda, so why isn't its price elasticity the same as the price elasticity for soda as a product?

6.3

The Relationship between Price Elasticity of Demand and Total Revenue, pages 251–255

LEARNING OBJECTIVE: Explain the relationship between the price elasticity of demand and total revenue.

Summary

Total revenue is the total amount of funds received by a seller of a good or service. When demand is inelastic, a decrease in price reduces total revenue, and an increase in price raises total revenue. When demand is elastic, a decrease in price increases total revenue, and an increase in price decreases total revenue. When demand is unit elastic, an increase or a decrease in price leaves total revenue unchanged.

Review Questions

- 3.1 If the demand for orange juice is inelastic, will an increase in the price of orange juice increase or decrease the revenue that orange juice sellers receive?
- 3.2 The price of organic apples falls, and apple growers find that their revenue increases. Is the demand for organic apples elastic or inelastic?

Problems and Applications

- 3.3 A sportswriter writing about the Cleveland Indians baseball team made the following observation: “If the Indians suddenly slashed all tickets to \$10, would their attendance actually increase? Not all that much and revenue would drop dramatically.” What is the sportswriter assuming about the price elasticity of demand for Indians tickets?

- 3.5 It has become customary for Transport for London (TFL), which is the local government body responsible for the transport system in town, to introduce new fares for transport services at the beginning of each year. In the last decade all increases have constantly been higher than the inflation rate.

What does this price strategy reveal about the beliefs of TFL regarding price elasticity of local transport in London? Briefly explain the reasons for your answer.

- 3.6 Coca-Cola has been focusing on selling more 7.5-ounce cans in displays near supermarket checkout lines. Previously, Coke had relied more heavily on 20-ounce bottles displayed in the beverage sections of supermarkets. An article in the *Wall Street Journal* noted that, “The smaller 7.5 ounce mini-cans are typically priced at five to seven cents an ounce, compared with three or four cents an ounce for 12-ounce cans.” It quoted a Coca-Cola executive as arguing that consumers “don’t care about the price. They will pick it up if you put Coke within arm’s reach.”
- a. What is the Coca-Cola executive assuming about the price elasticity of demand for Coke? Briefly explain.
- b. If the executive is correct, what will the effect of this marketing strategy be on the firm’s revenues from selling Coke? Briefly explain.
- c. Why did the executive believe that having the cans “within arm’s reach” in the checkout line was important? Could this positioning have an effect on the price elasticity of demand? Briefly explain.

- 3.7 Use the following graph for Yolanda’s Frozen Yogurt Stand to answer the questions on the next page.

- a. Use the midpoint formula to calculate the price elasticity of demand for D_1 between point A and point C and the price elasticity of demand for D_2 between point A and point B. Which demand curve is more elastic, D_1 or D_2 ? Briefly explain.
- b. Suppose Yolanda is initially selling 200 cones per day at a price of \$3.00 per cone. If she cuts her price to \$2.50 per cone and her demand curve is D_1 , what will be the change in her revenue? What will be the change in her revenue if her demand curve is D_2 ?

3.8 (Related to Solved Problem 6.3 on page 253) Briefly explain whether you agree with Manager 2's reasoning:

Manager 1: "The only way we can increase the revenue we receive from selling our frozen pizzas is by cutting the price."

Manager 2: "Cutting the price of a product never increases the amount of revenue you receive. If we want to increase revenue, we have to increase the price."

3.9 (Related to Solved Problem 6.3 on page 253) According to a company news release, during the third quarter of 2014, the Coca-Cola Company sold 1 percent less soda in North America while earning more revenue.

- 3.10 (Related to the Making the Connection on page 254)** According to an article in the *New York Times*, some small publishers have argued that Amazon has been increasing the prices it charges for their books on its Web site. Amazon was increasing the prices by reducing the discount it offered consumers on the retail prices of the books. One small nonfiction publisher said that Amazon had reduced the discount on its books from about 30 percent to about 16 percent. According to the author of the article, "For this publisher, that means less revenue and less profit as some buyers reject the more expensive books."

- a. Does the fact that some buyers will no longer buy the publisher's books at a higher price necessarily mean the publisher will earn less revenue? Briefly explain.
- b. What must be true about the price elasticity of demand for the publisher's books for the author's statement to be correct?

Other Demand Elasticities, pages 255–257

LEARNING OBJECTIVE: Define cross-price elasticity of demand and income elasticity of demand and understand their determinants and how they are measured.

Summary

In addition to the price elasticity of demand, other important demand elasticities are the **cross-price elasticity of demand**, which is equal to the percentage change in the quantity demanded of one good divided by the percentage change in the price of another good, and the **income elasticity of demand**, which is equal to the percentage change in the quantity demanded divided by the percentage change in income.

- 4.6 (Related to the Chapter Opener on page 241) According to an article on the *Boston Globe's* Web site, during the last three months of 2014, gasoline prices dropped

33 percent at the same time as ridership on mass transit, such as subways and trains, increased by 1 percent. According to a spokesperson for the American Public Transportation Association, a group that lobbies Congress on behalf of public transit systems, "Even with gas prices dropping like a rock, the public is still demanding more transit options."

- On the basis of this information, is the cross-price elasticity of demand between gasoline and rides on mass transit positive or negative? Would you conclude that gasoline and rides on mass transit are substitutes or complements? Briefly explain.
- During this period unemployment was declining, and the news story also included the observation, "An improving economy means more people need to get to work." Does this observation cause you to modify your answer to part (a)? Briefly explain.

Using Elasticity to Analyze the Disappearing Family Farm, pages 258–260

LEARNING OBJECTIVE: Use price elasticity and income elasticity to analyze economic issues.

Summary

Price elasticity and income elasticity can be used to analyze many economic issues. One example is the disappearance of the family farm in the United States. Because the income elasticity of demand for food is low, the demand for food has not increased proportionally as incomes in the United States have grown. As farmers have become more productive, they have increased the supply of most foods. Because the price elasticity of demand for food is low, increasing supply has resulted in continually falling food prices.

- 5.2 (Related to Solved Problem 6.5 on page 259) According to a study by the U.S. Centers for Disease Control and Prevention, the price elasticity of demand for cigarettes is -0.25 . Americans purchase about 360 billion cigarettes each year.

- If the federal tax on cigarettes were increased enough to cause a 50 percent increase in the price of cigarettes, what would be the effect on the quantity of cigarettes demanded?
- Is raising the tax on cigarettes a more effective way to reduce smoking if the demand for cigarettes is elastic or if it is inelastic? Briefly explain.

- 5.4** Corruption has been a significant problem in Iraq. Opening and running a business in Iraq usually requires paying multiple bribes to government officials. We can think of there being a demand and supply for bribes, with the curves having the usual shapes: The demand for bribes will be downward sloping because the smaller the bribe, the more business owners will be willing to pay it. The supply of bribes will be upward sloping because the larger

the bribe, the more government officials will be willing to run the risk of breaking the law by accepting the bribe. Suppose that the Iraqi government introduces a new policy to reduce corruption that raises the cost to officials of accepting bribes—perhaps by increasing the jail term for accepting a bribe. As a result, the supply curve for bribes will shift to the left. If we measure the burden on the economy from corruption by the total value of the bribes paid, what must be true of the demand for bribes if the government policy is to be effective? Illustrate your answer with a demand and supply graph. Be sure to show on your graph the areas representing the burden of corruption before and after the government policy is enacted.

- The federal government is considering implementing a price floor in the market for kumquats. The government will not be able to buy any surplus kumquats produced at the price floor or to pay us any other subsidy. Because the demand for kumquats is elastic, I believe this program will make us worse off, and I say we should oppose it.
- Explain whether you agree with this reasoning.
- 5.6** Review the concept of economic efficiency from Chapter 4, pages 173–175, before answering the following question: Will there be a greater loss of economic efficiency from a price ceiling when demand is elastic or inelastic? Illustrate your answer with a demand and supply graph.

6.6

The Price Elasticity of Supply and Its Measurement, pages 260–264

LEARNING OBJECTIVE: Define *price elasticity of supply* and understand its determinants and how it is measured.

Summary

The **price elasticity of supply** is equal to the percentage change in quantity supplied divided by the percentage change in price. The supply curves for most goods are inelastic over a short period of time, but they become increasingly elastic over longer periods of time. Perfectly inelastic supply curves are vertical lines, and perfectly elastic supply curves are horizontal lines. Relatively few products have perfectly elastic or perfectly inelastic supply curves.

How Much Will You Pay for Health Insurance?

Australian public spending on healthcare has been growing at a rate faster than education, social security and welfare expenditure. Its percentage of GDP was 9.1 percent in 2014–15. The share of healthcare spending of total public expenses accelerated from 14 percent in 2000–01 to 16.6 percent in 2014–15.

Health expenses increased due to the increase in the contraction of chronic diseases, higher demand for expensive health services, and an ageing population. To meet these challenges, the Australian government decided to overhaul its health care system. Aiming to provide equitable and comprehensive care for all Australians over their lifetime, the *National Health and Hospitals Reform Commission* was established in 2008. The *National Health Reform Agreement* was signed in 2011, conjoining individual and collective action to introduce good health care. *Medicare* comprises almost 43 percent of the total public health spending. Typically, *Medicare* covers 100 percent of Australian residents' in-hospital costs, 75 percent of General Practitioner fees and 85 percent of specialist services. The scheme is partly funded by taxpayers who pay a *Medicare Levy* of 2 percent of their taxable income. Households with income lower than AUS \$20,896 are exempt.

To reduce the demand on the public *Medicare* system, the government uses a combination of surcharges and incentives. A *Medicare Levy Surcharge* is levied above the base income threshold for Australian residents who have not purchased an appropriate level of private health insurance coverage. The People are incentivized to buy private insurance through the *Private Health Insurance Rebate*, a federal government subsidy for the cost of insurance.

Australian employers are not legally obliged to buy health insurance coverage for employees, but firms often provide private health care coverage as part of a general employee benefit scheme. As an incentive, the tax authorities provide tax rebates or returns to the beneficiary employee equivalent to the premium amount paid. These measures have resulted in 45 percent of Australians purchasing private health insurance. But as the *National Health Reform Agreement* was signed only in 2011 its effects on health care expenditure and overall health improvements remains to be seen.

Economics in Your Life

Is Your Take-Home Pay Affected by What Your Employer Spends on Your Health Insurance?

If you work for a firm that offers you health insurance, the firm will withhold some amount from each of your paychecks to pay for the insurance. Typically, firms pay the majority of the cost of health insurance for their employees. In 2014, employees paid only 18 percent of the cost of coverage for themselves or 29 percent of the cost of coverage for their family. Your paycheck probably doesn't show the amount your employer pays on your behalf for health insurance, but does that amount affect your take-home pay? As you read this chapter, try to answer this question. You can check your answer against the one we provide on **page 301** at the end of this chapter.

Health care Goods and services, such as prescription drugs, consultations with a doctor, and surgeries, that are intended to maintain or improve a person's health.

Health care refers to goods and services, such as prescription drugs, consultations with a doctor, and surgeries, that are intended to maintain or improve a person's health. Health care makes up more than one-sixth of the U.S. economy—about the size of the entire economy of France. Improvements in health care are an important part of the tremendous increase in living standards people in the United States and other high-income countries have experienced over the past 100 years. Health care has seen rapid technological change with new products, such as MRI units and other diagnostic equipment; prescription drugs to treat cancer, high blood pressure, and AIDS; vaccinations for meningitis; and new surgical techniques, such as cardiac catheterizations for treatment of heart disease.

Health care is provided through markets, just as are most other goods and services, such as smartphones and haircuts. So, we can apply to health care the tools of economic analysis we used in previous chapters. But the market for health care is different from other markets. In the United States, doctors and hospitals that supply most health care are primarily private firms, but the government also provides some health care services directly through the Veterans Health Administration, which is part of the U.S. Department of Veterans Affairs, and indirectly through the Medicare and Medicaid programs.

In addition to having a large role for government, the market for health care differs from most markets in other ways. Most importantly, a typical consumer of health care doesn't pay full price for that care. Most people have private health insurance, either provided through their employers or purchased on the government-run health insurance marketplaces, or they are enrolled in the Medicare or Medicaid programs. Consumers who have insurance make different decisions about the quantity of health care they wish to consume than they would if they were paying the full cost of the services. So, to analyze the market for health care, we will need to use economic tools beyond those introduced in previous chapters. We begin our analysis of health care with an overview of health care around the world.

7.1 The Improving Health of People in the United States

LEARNING OBJECTIVE: Use data to discuss trends in U.S. health over time.

Two hundred years ago, the whole world was very poor by modern standards. Today, an average person in a high-income country has a standard of living well beyond what even the richest people in the past could have imagined. One aspect of this higher standard of living is the improved health the average person enjoys. For example, in the late 1700s, England had the highest level of income per person of any large country. But the average person in England had a short life span and many people suffered from diseases—such as cholera, yellow fever, dysentery, and smallpox—that have disappeared from high-income countries today. The average life expectancy at birth was only 38 years, and 30 percent of the population died before reaching age 30. Even people who survived to age 20 could expect to live only an average of 34 more years. Today, the average life expectancy at birth in the United Kingdom and other high-income countries is around 80 years. People in eighteenth-century England were also short by modern standards. The average height of an adult male was 5 feet, 5 inches compared with 5 feet, 9 inches today.

In this section, we discuss the health of people in the United States. In Section 7.2, we discuss health care in other countries.

Variable	1850	2015
Life expectancy at birth	38.3 years	79.6 years
Average height (adult males)	5'7"	5'9.5"
Infant mortality (death of a child aged 1 year or less)	228.9 per 1,000 live births	6.2 per 1,000 live births

Note: The data on heights for 1850 include only native-born white and black male citizens. The data on height for 2015 were gathered in 2007–2010 and represent the median height of adult males 20 years and older.

Changes over Time in U.S. Health

When economists measure changes over time in the standard of living in a country, they usually look first at increases in income per person. However, changes in health are also important because health is an essential part of a person's well-being and, therefore, of his or her standard of living. The health of the average person in the United States improved significantly during the nineteenth and twentieth centuries, and by and large, it continues to improve today.

Table 7.1 compares three indicators of health in the United States in 1850 and 2015. Individuals in the United States today are taller, live much longer, and are much less likely to die in the first months of life than was true 165 years ago. Economists often use height as a measure of long-run changes in the average well-being of a population. A person's height depends partly on genetics—that is, tall parents tend to have tall children—but also on a person's *net nutritional status*. Net nutritional status depends on a person's food intake relative to the work the person has to perform, whether the person is able to remain warm in cold weather, and the diseases to which the person is exposed. Over time, people in the United States and other high-income countries have, on average, become taller, which is an indication that their nutritional status has improved.

Reasons for Long-Run Improvements in U.S. Health

For most of the country's history, the health of people in the United States has steadily improved, with life expectancies increasing and death rates decreasing. Panel (a) of Figure 7.1 shows for the years 1900–2013 the increase in life expectancy and the decline in the mortality rate, or death rate, measured as deaths per 100,000 people. Note that the mortality rate is “age adjusted,” which means that it is not affected by changes in the number of people in each age group. Life expectancy at birth in the United States increased from 47.3 years in 1900 to 79.6 years in 2015. Panel (b) shows for recent years the change in the overall mortality rate of the U.S. population, measured as deaths per 100,000 people, and the age-adjusted mortality rates for several diseases. The overall mortality rate decreased by more than 25 percent between 1981 and 2013. Over this same period, deaths from cancer, cardiovascular disease, such as heart attacks and strokes, and diseases of the liver all declined significantly. For example, cancer deaths were 20 percent lower in 2013 than they were in 1981, while deaths from cardiovascular disease declined by more than half during this time. Deaths from diabetes and kidney disease both increased slightly during this period, largely due to the effects of increasing obesity. The overall decline in death rates in the United States since 1981 was due to changes in lifestyle, particularly a decline in smoking, and advances in new diagnostic equipment, prescription drugs, and surgical techniques.

What explains increases in life expectancy and declines in death rates in the years since 1850? Improvements in sanitation and in the distribution of food during the late 1800s and early 1900s led to better health during that period. More generally, the late Nobel Laureate Robert Fogel of the University of Chicago and Roderick Floud of Gresham College, along

Since 1900, life expectancy has increased and mortality rates have decreased in the United States. Since 1981, there have been significant decreases in rates of death due to cancer, cardiovascular diseases, and diseases of the liver. Rates of death due to kidney disease and diabetes increased slightly because of an increase in obesity. Note that in panel (a), the increase in mortality and decrease in life expectancy in 1918 are due to the severe influenza epidemic of that year.

with coauthors, have described a process by which better health makes it possible for people to work harder as they become taller, stronger, and more resistant to disease. Working harder raises a country's total income, making it possible for the country to afford better sanitation, more food, and a better system for distributing the food. In effect, improving health shifts out a country's production possibilities frontier. Higher incomes also allow the country to devote more resources to research and development, including medical research. The United States has been a pioneer in the development of medical technology, new surgical techniques, and new pharmaceuticals, which have played important roles in lengthening life spans and reducing the death toll from diseases.

7.2 Health Care around the World

LEARNING OBJECTIVE: Compare the health care systems and health care outcomes in the United States and other countries.

In the United States, private firms provide most health care, through either doctors' practices or hospitals. The main exception is the care the government provides through the network of hospitals operated by the federal government's Veterans Administration, although some cities also own and operate hospitals. Governments in most countries outside the United States have a more substantial direct role in paying for or providing health care. Policymakers and economists debate the effects of greater government involvement in the health care system on health outcomes such as life expectancy, infant mortality, and successful treatment of diseases.

Health insurance A contract under which a buyer agrees to make payments, or *premiums*, in exchange for the provider's agreeing to pay some or all of the buyer's medical bills.

The U.S. Health Care System

One important difference among health care systems in different countries is the way people pay for their health care. Most people in the United States have *health insurance* that helps them to pay their medical bills. **Health insurance** is a contract

under which a buyer agrees to make payments, or *premiums*, in exchange for the provider's agreeing to pay some or all of the buyer's medical bills. Figure 7.2 shows the sources of health insurance in the United States in 2014. Some people have insurance of more than one type by, for example, participating in a government insurance program such as Medicare as well as having a private insurance policy. About 55 percent of people received health insurance through their employer, and about 15 percent directly purchased an individual or family health insurance policy from an insurance company. About 36 percent of people received health insurance through a government program including Medicaid, Medicare, and the program run by the Department of Veterans Affairs. About 10 percent of people were uninsured.

Most people who have private health insurance receive it through their employer. In 2014, about 98 percent of firms employing more than 200 workers and about 54 percent of firms employing between 3 and 199 workers offered health insurance as a fringe benefit (that is, a type of non-wage compensation) to their employees. Private health insurance companies can be either not-for-profit firms, such as some of the Blue Cross and Blue Shield organizations, or for-profit firms, such as Aetna and John Hancock, which typically also sell other types of insurance. Private health insurance companies sell *group plans* to employers to cover all of their employees and individual plans directly to the public. Some health insurance plans reimburse doctors and hospitals on a **fee-for-service** basis, which means that doctors and hospitals receive a payment for each service they provide. Other health insurance plans are organized as *health maintenance organizations* (HMOs), which typically reimburse doctors mainly by paying a flat fee per patient rather than paying a fee for each individual office visit or other service provided.

About 10 percent of people were not covered by health insurance in 2014. This percentage was lower than in previous years, partly as a result of passage of the Affordable Care Act in 2010, but still represented millions of uninsured people. Many people lack health insurance because their incomes are low, and they believe they cannot afford to buy private health insurance even with government subsidies. Some low-income people either do not qualify for Medicaid or choose not to participate in that program. About 70 percent of uninsured people live in families in which at least one member has a job. These individuals either were not offered health insurance through their employers or chose not to purchase it. Some young people opt out of employer-provided health insurance because they are healthy and do not believe that the cost of the premium their employer charges for the insurance is worth the benefit of having the insurance. More than half the uninsured were younger than age 35. Although most large firms offer their employees health insurance, fewer than two-thirds accept it. The remaining employees are covered by a spouse's policy, are not eligible for coverage, or have decided to go uninsured because they do not want to pay the premium for the insurance. The uninsured must pay for their own medical bills *out of pocket*, with money

The Increasing Importance of Health Care in the U.S. Economy

When you graduate from college, you are much more likely than your parents or grandparents were to get a job in health care. There are many types of jobs in health care, from doctors and nurses to managers at hospitals and nursing homes to researchers and salespeople at pharmaceutical firms. As the following maps show, in 1990, manufacturing was the largest source of employment in most states, and in no state was health care the largest employer. By 2000, manufacturing was still the largest employer in 27 states, but health care had become the largest employer in two states. The results for 2014 are strikingly different, with manufacturing the largest employer in only 7 states and health care the largest employer in 34 states.

(a) In 1990, manufacturing was the largest source of employment in most states.

(b) In 2000, manufacturing was still the largest employer in 27 states, but health care had become the largest employer in 2 states.

(c) In 2014, manufacturing was the largest employer in only 7 states, and health care was the largest employer in 34 states.

In 1990, almost twice as many people in the United States worked in manufacturing as worked in health care. Today, employment in health care has doubled, while employment in manufacturing has declined by more than 30 percent. And these trends are likely to continue. The U.S. Bureau of Labor Statistics forecasts that 13 of the 20 fastest-growing occupations over the next 10 years will be in health care.

What explains these trends? We discuss explanations for rising health care spending in the United States in Section 7.4. For now, note that the growth of employment in health care is similar to that in other service industries, such as retail stores and restaurants, and that the growth of employment in the health care and service industries is much faster than that in goods-producing industries, such as manufacturing. In addition, there is evidence that as people's incomes grow, their demand for health care grows faster than their demand for most other goods and services. The average age of the U.S. population is also increasing, and older people have a greater demand for health care. Finally, the Affordable Care Act has increased the demand for health care among low-income people in two ways: by providing subsidies to buy health insurance for people whose incomes fall below a certain level and by expanding the Medicaid system.

It seems likely that health care will continue to be a booming sector of the economy and an important source of new jobs in the coming decades.

The Health Care Systems of Canada, Japan, and the United Kingdom

In many countries, such as Canada, Japan, and the United Kingdom, the government either supplies health care directly by operating hospitals and employing doctors and nurses or pays for most health care expenses, even if hospitals are not government owned and doctors are not government employees. In this section, we look briefly at the health care systems in three countries.

Canada Canada has a **single-payer health care system**, in which the government provides *national health insurance* to all Canadian residents. Each of the 10 Canadian provinces has its own system, although each system must meet the federal government’s requirement of covering 100 percent of the cost of all medically necessary procedures. Individuals pay nothing for doctor’s visits or hospital stays; instead, they pay for medical care indirectly through the taxes they pay to the provincial and federal governments. As in the United States, most doctors and hospitals are private businesses, but unlike in the United States, doctors and hospitals are required to accept the fees that are set by the government. Also as in the United States, doctors and hospitals are typically reimbursed on a fee-for-service basis.

Single-payer health care system A system, such as the one in Canada, in which the government provides health insurance to all of the country’s residents.

Japan Japan has a system of *universal health insurance* under which every resident of the country is required to enroll either in one of the many nonprofit health insurance societies that are organized by industries or professions or in the health insurance program provided by the national government. The system is funded by a combination of premiums paid by employees and firms and a payroll tax similar to the tax that funds the Medicare program in the United States. Unlike the Canadian system, the Japanese system requires substantial *copayments*, under which patients pay as much as 30 percent of their medical bills, while health insurance pays for the rest. Japanese health insurance does not pay for most preventive care, such as annual physical exams, or for medical expenses connected with pregnancies, unless complications result. Health insurance in the United States and Canada typically does cover these expenses. As in the United States, most doctors in Japan do not work for the government, and there are many privately owned hospitals. The number of government-run hospitals, though, is greater than in the United States.

The United Kingdom In the United Kingdom, the government, through the National Health Service (NHS), owns nearly all hospitals and directly employs nearly all doctors. This system contrasts with those in the United States, Canada, and Japan, where the government employs relatively few doctors and owns relatively few hospitals. Because there are few private insurance plans and private hospitals in the United Kingdom, its health care system is often called **socialized medicine**. With 1.7 million employees, the NHS is the largest government-run health care system in the world. Apart from a small copayment for prescriptions, the NHS supplies health care services without charge to patients because it receives its funding from income taxes. The NHS concentrates on preventive care and care for acute conditions. Nonemergency care, also called elective care—such as hip replacements, knee surgery following a sports injury, or reconstructive surgery following a mastectomy—is a low priority. The NHS’s goals result in waiting lists for elective procedures that can be very long, with patients sometimes waiting a year or more for a procedure that would be available in a few weeks or less in the United States. To avoid the waiting lists, more than 10 percent of the population also has private health insurance, frequently provided by employers, which the insured use to pay for elective procedures.

Socialized medicine A health care system under which the government owns most of the hospitals and employs most of the doctors.

The NHS essentially trades off broader coverage for longer waiting times and performing fewer procedures, particularly nonemergency surgeries. MyEconLab Concept Check

Comparing Health Care Outcomes around the World

We have seen that the way health care systems are organized varies significantly across countries. Health care outcomes and the amounts countries spend on health care are also quite different. As Figure 7.3 shows, typically, the higher the level of income per person in a country, the higher the level of spending per person on health care. This result is not surprising because health care is a *normal good*. We know that as income increases, so does spending on normal goods (see Chapter 3, Section 3.1). The line in the figure shows the average relationship between income per person and health care spending per person. The dots for most countries are fairly close to the line, but note that the dot representing the United States is significantly above the line. Being well above the line indicates that health care spending per person in the United States is higher than in other countries, even taking into account the relatively high income levels in the United States. In Section 7.4, we will discuss explanations for the high level of health care spending in the United States.

Has the high level of health care spending in the United States resulted in better health outcomes? Are people in the United States healthier, and do they have their medical problems addressed more rapidly than do people in other countries? Table 7.2 compares several health outcomes for the countries that are members of the Organization for Economic Co-operation and Development (OECD), a group of 34 high-income countries. The table shows that the United States does relatively poorly with respect to infant mortality, while it does about average with respect to life expectancy. People in the United States are more likely to be obese than are people in other countries, which can lead to developing diabetes and other health problems.

The United States rates well in the availability of medical equipment that can be used in diagnosing and treating illness. Table 7.2 shows that the United States has nearly three times as many MRI units and over 50 percent more CT scanners than the average of European countries, although the United States has relatively fewer of these machines than does Japan. The United States also appears to do well in cancer treatment with a lower rate of cancer deaths and a relatively low mortality ratio from cancer. The mortality ratio measures the rate at which people die from cancer relative to the rate at which they are diagnosed with cancer. A low cancer mortality ratio indicates that the U.S. health care system does a relatively good job of reducing the death rate among people diagnosed with cancer.

How useful are cross-country comparisons of health outcomes in measuring the effectiveness of different health care systems? Health economists and other researchers disagree strongly about the answer to this question. Here are some factors that make cross-country comparisons in health outcomes difficult:

- **Data problems.** Countries do not always collect data on diseases and other health problems in the same way. So, there are not enough consistent data available to compare health outcomes for more than a few diseases.
- **Problems with measuring health care delivery.** The easiest outcomes to measure are deaths because a specific event has occurred. So, measures of life expectancy, infant mortality, and mortality rates from some diseases, such as cancer, are available across countries. But much of health care involves treatment for injuries, simple surgical procedures, writing of pharmaceutical prescriptions, and other activities for which outcomes are difficult to measure. For example, although the United Kingdom does well in many of the measures shown in Table 7.2, patients have long waiting times for elective surgical procedures that can be arranged much more quickly in some other countries, including the United States. Economists have difficulty measuring the cost to patients of these waiting times.
- **Problems with distinguishing health care effectiveness from lifestyle choices.** Health outcomes depend partly on the effectiveness of doctors and hospitals in delivering medical services. But they also depend on the choices of individuals. For example, in the United States, the high rates of obesity and hospitalizations for diabetes—which can be a complication of obesity—may be caused more by the decisions individuals make about diet and exercise than by the effectiveness of the U.S. health care system.
- **Problems with determining consumer preferences.** In most markets, we can assume that the quantities and prices we observe reflect the interactions of the

preferences of consumers (demand) with the costs to firms of producing goods and services (supply). Given their incomes and preferences, consumers compare the prices of different goods and services when making their buying decisions. The prices firms charge represent the costs of providing the good or service. In the market for health care, however, the government plays the dominant role in supplying the service in most countries other than the United States, so the cost of the service is not fully represented in its price, which in some countries is zero. Even in countries where consumers must pay for medical services, the prices they pay usually do not represent the cost of providing the service. In the United States, for instance, consumers with private health insurance typically pay only 10 to 20 percent of the price as a copayment. For these reasons, it is difficult to determine whether some countries do a better job than others in providing health care services whose cost and effectiveness are consistent with consumer preferences.

7.3 Information Problems and Externalities in the Market for Health Care

LEARNING OBJECTIVE: Define information problems and externalities, and explain how they affect the market for health care.

Asymmetric information A situation in which one party to an economic transaction has less information than the other party.

The market for health care is significantly affected by the problem of **asymmetric information**, which occurs when one party to an economic transaction has less information than the other party. Understanding the concept of asymmetric information can help us analyze the actions of buyers and sellers of health care and health insurance and the actions of the government in the health care market. The consequences of asymmetric information may be easier to understand if we first consider its effect on the market for used automobiles, which is the market in which economists first began to carefully study this problem.

Adverse Selection and the Market for “Lemons”

Nobel Laureate George Akerlof of Georgetown University pointed out that the seller of a used car will always have more information on the true condition of the car than will potential buyers. For example, a car that has not had its oil changed regularly may have damage that even a trained mechanic may have difficulty detecting.

If potential buyers of used cars know that they will have difficulty distinguishing good used cars from bad used cars, or “lemons,” they will take this into account in the prices they are willing to pay. Consider the following simple example: Suppose that half of the 2013 Volkswagen Jettas offered for sale have been well maintained and are good, reliable used cars. The other half have been poorly maintained and are lemons that will be unreliable. Suppose that potential buyers of 2013 Jettas would be willing to pay \$10,000 for a reliable one but only \$5,000 for an unreliable one. The sellers know how well they have maintained their cars and whether they are reliable, but the buyers do not have this information and so have no way of distinguishing the reliable used cars from the unreliable ones.

In this situation, buyers will generally offer a price somewhere between the price they would be willing to pay for a good car and the price they would be willing to pay for a lemon. With a 50–50 chance of buying a good car or a lemon, buyers might offer \$7,500, which is halfway between the price they would pay if they knew for certain the car was a good one and the price they would pay if they knew it was a lemon.

Unfortunately for used car buyers, a major glitch arises at this point. From the buyers’ perspective, given that they don’t know whether any particular car offered for sale is a good car or a lemon, an offer of \$7,500 seems reasonable. But the sellers do know whether the cars they are offering are good cars or lemons. To a seller of a good car, an offer of \$7,500 is \$2,500 below the true value of the car, and the seller will be reluctant to sell. But to a seller of a lemon, an offer of \$7,500 is \$2,500 above the true value

of the car, and the seller will be quite happy to sell. As sellers of lemons take advantage of knowing more about the cars they are selling than buyers do, buyers in the used car market will fall victim to **adverse selection**: Most used cars offered for sale will be lemons. In other words, because of asymmetric information, the market has selected adversely the cars that will be offered for sale. Notice as well that the problem of adverse selection reduces the total quantity of used cars bought and sold in the market because few good cars are offered for sale.

MyEconLab Concept Check

Adverse selection The situation in which one party to a transaction takes advantage of knowing more than the other party to the transaction.

Asymmetric Information in the Market for Health Insurance

Asymmetric information problems are particularly severe in the markets for all types of insurance, including health insurance. To understand this point, first consider how insurance works. Insurance companies provide the service of *risk pooling* when they sell policies to households. For example, if you own a \$150,000 house but do not have a fire insurance policy, a fire that destroys your house can be a financial catastrophe. But an insurance company can pool the financial risk of your house burning down by selling fire insurance policies to you and thousands of other homeowners. Homeowners are willing to accept the certain cost represented by the premium they pay for insurance in return for eliminating the uncertain—but potentially very large—cost should their house burn down.

Notice that for the insurance company to cover all of its costs, the total amount it receives in premiums must be greater than the amount it pays out in claims to policyholders. To survive, insurance companies have to predict accurately the amount they are likely to pay out to policyholders. For instance, if an insurance company predicts that the houses of only 2 percent of policyholders will burn down during a year when 5 percent of houses actually burn down, the company will suffer losses. However, if the company predicts that 8 percent of houses will burn down when only 5 percent actually do, the company will have charged premiums that are too high. A company that charges premiums that are too high will lose customers to other companies and may eventually be driven out of business.

Adverse Selection in the Market for Health Insurance One obstacle to health insurance companies accurately predicting the number of claims policyholders will make is that buyers of health insurance policies always know more about the state of their health—and, therefore, how likely they are to submit medical bills for payment—than will the insurance companies. In other words, insurance companies face an adverse selection problem because sick people are more likely to want health insurance than are healthy people. If insurance companies have trouble determining who is healthy and who is sick, they are likely to sell policies to more sick people than they had expected, with the result that the premiums they charge will be too low to cover their costs.

An insurance company faces a financial problem if the premiums it is charging are too low to cover the costs of the claims being submitted. The company might try to increase the premiums it charges, but this may make the adverse selection problem worse. If premiums rise, then younger, healthier people who rarely visit the doctor may respond to the increase in premiums by dropping their insurance. The higher premiums have made the adverse selection problem worse for the insurance company because it will have fewer healthy policyholders than it had before the premium increase. The situation is similar to that facing a used car buyer who knows that adverse selection is a problem in the used car market and decides to compensate for it by lowering the price he is willing to pay for a car. The lower price will reduce the number of sellers of good cars willing to sell to him, making his adverse selection problem worse.

One way to deal with the problem of adverse selection is for the government to require every person to buy insurance. Most states require all drivers to buy automobile insurance so that both high-risk and low-risk drivers will carry insurance. The Patient Protection and Affordable Care Act (ACA) passed in 2010 requires that residents of the United States must buy health insurance or pay a fine. This provision of the law is known as the *individual mandate* and has been controversial. We discuss it further in Section 7.4.

Moral hazard The actions people take after they have entered into a transaction that make the other party to the transaction worse off.

Moral Hazard in the Market for Health Insurance The insurance market is subject to a second consequence of asymmetric information. **Moral hazard** refers to actions people take after they have entered into a transaction that make the other party to the transaction worse off. Moral hazard in the insurance market occurs when people change their behavior after becoming insured. For example, once a firm has taken out a fire insurance policy on a warehouse, its managers might be reluctant to install an expensive sprinkler system. Similarly, someone with health insurance may visit the doctor for treatment of a cold or other minor illness, which he would not do if he lacked insurance. Or someone with health insurance might engage in risky activities, such as riding a motorcycle, which she would not do if she lacked insurance.

One way to think about the basic moral hazard problem with insurance is to note that normally there are two parties to an economic transaction: the buyer and the seller. The insurance company becomes a third party to the purchase of medical services because the insurance company, rather than the patient, pays for some or all of the service. For this reason, economists refer to traditional health insurance as a *third-party payer* system. Because of this system, consumers of health care do not pay a price that reflects the full cost of providing the service. This lower price leads consumers to use more health care than they otherwise would.

Don't Let This Happen to You

Don't Confuse Adverse Selection with Moral Hazard

The two key consequences of asymmetric information are adverse selection and moral hazard. It is easy to mix up these concepts. One way to keep the concepts straight is to remember that adverse selection refers to what happens at the time of entering into a transaction. An example would be an insurance company selling a life insurance policy to a terminally ill person because the company lacks full

information on the person's health. Moral hazard refers to what happens after entering into a transaction, such as a nonsmoker buying a life insurance policy and then starting to smoke four packs of cigarettes a day. (It may help to remember that *a* comes before *m* alphabetically, just as adverse selection comes before moral hazard.)

Your Turn: Test your understanding by doing related problems 3.9 and 3.10 on page 304 at the end of this chapter.

Principal-agent problem A problem caused by agents pursuing their own interests rather than the interests of the principals who hired them.

Third-party payer health insurance can also lead to another consequence of moral hazard, known as the *principal-agent problem*, because doctors may be led to take actions that are not necessarily in the best interests of their patients, such as increasing their incomes by prescribing unnecessary tests or other treatments for which the doctors receive payment. The **principal-agent problem** results from agents—in this case, doctors—pursuing their own interests rather than the interests of the principals—in this case, patients—who hired them. If patients had to pay the full price of lab tests, MRI scans, and other procedures, they would be more likely to question whether the procedures were really necessary. Because health insurance pays most of the bill for these procedures, patients are more likely to accept them. Note that the fee-for-service aspect of most health insurance in the United States can make the principal-agent problem worse because doctors and hospitals are paid for each service performed, whether or not the service was necessary or effective.

The number of medical procedures performed in the United States has been continually increasing. Many doctors argue that the increasing number of medical procedures is not the result of third-party payer health insurance. Instead, the increase is due to the improved effectiveness of the procedures in diagnosing illness and the tendency of some doctors to practice “defensive medicine” because they fear that if they fail to correctly diagnose an illness, a patient may file a malpractice lawsuit against them.

How Insurance Companies Deal with Adverse Selection and Moral Hazard

Insurance firms use cost-sharing measures to buffer themselves against adverse selection and moral hazard problems. The most common of these cost-sharing procedures are deductibles, co-insurance, and co-payments. A deductible is a fixed annual amount that the policyholder must pay toward the cost of health care bills before the insurance firm starts to provide coverage. Co-payments and co-insurance are agreements between the insured and the health insurance company which requires the policy holder to cover either a fixed amount or a set percentage of the health services usually after having met annual deductibles.

For example, each of Mr. Gonzales, Ms Ortega and Mrs Lopez purchase a health-care insurance plan in Chilean pesos with CLP 1,200,000 (equivalent to €1,800) annual deductible. Mr. Gonzales buys a health insurance policy that provides 20 percent co-insurance, while both of Ms Ortega and Mrs Lopez prefer to buy a policy with a flat fixed co-payment of CLP 25,000 per health service. Suppose that Mr. Gonzales got sick two months after meeting the deductible. The physician's bill is CLP 100,000. Mr. Gonzales' coinsurance payment of 20 percent would be CLP 20,000. The health insurance firm pays the rest of the amount, that is, CLP 80,000. Now suppose that Ms Ortega breaks her leg after paying only CLP 500,000 towards her deductible. She has to pay 100 percent of her medical bills until her deductible reaches CLP 1,200,000. Mrs Lopez visits her doctor after having fully paid the deductible of CLP 1,200,000. The doctor's bill is around CLP 35,000. Her insurance company pays CLP 25,000 while she covers CLP 10,000.

Deductibles, coinsurance, and co-payments make the policies less attractive to people who intend to file many claims, thereby reducing the adverse selection and moral hazard problems. However, they reduce, but hardly eliminate adverse selection and moral hazard. People who expect to have hefty medical expenses will still have a greater incentive to buy health insurance. Similarly, those who buy health insurance are more likely to visit physicians even for minor illnesses.

The Chilean law obliges workers to spend at least 7 percent of their taxable income on either private or public health insurance. While public insurance sets its premiums as a percentage of income, private insurance firms can use risk rating and adjust their premiums according to age, sex, and dependents. Accordingly, Chileans with higher risk factors, age, and household size find public insurance more attractive. On the other hand, younger Chileans and those with higher income prefer to purchase private insurance. The median age in Chile is around 33–34 years, making it a predominantly young population. It is estimated per capita income of \$15,000 as on 2015 makes it among the highest in Latin America. These two factors explain why over 50 percent of the Chilean population prefers to purchase private insurance.

The case of Hong Kong is intriguingly different. This is because of the hybrid influence of the Chinese socio-ethnic medicine culture within a greatly westernized society. Even though per capita income in Hong Kong is higher than that of Chile, only 30 percent of the population in Hong Kong has private health insurance coverage. This is acquired either through employment-based programs or as riders on life insurance policies. The reason is that 70 percent of patients mostly resort to out-of-pocket self-management strategies or private fee-based Western or Chinese medicine practitioners. MyEconLab Concept Check

Externalities in the Market for Health Care

For most goods and services, we assume that the consumer receives all the benefits from consuming the good and that the firm producing the good bears all of the costs of production. Some goods or services, though, involve an *externality*, which is a benefit or cost that affects someone who is not directly involved in the production or consumption of a good or service. For example, if a utility burns coal to produce electricity, the result will be air pollution, which causes a *negative externality* because people with asthma or other breathing problems may bear a cost even though they were not involved in buying or selling the electricity that caused the pollution. College education may result in a *positive externality* because college-educated people are less likely to commit crimes and, by being better-informed voters, more likely to contribute to better government policies. So, although you receive most of the benefits of your college education, other people also receive some of the benefits.

Externalities interfere with the economic efficiency of a market equilibrium. A competitive market achieves economic efficiency by maximizing the sum of consumer surplus and producer surplus (see Chapter 4, Section 4.1). But when there is a negative externality in production, as with air pollution, the market will produce more than the efficient quantity. When there is a positive externality in consumption, as with college educations, the market will produce less than the efficient quantity. (A more complete discussion of externalities appears in Chapter 5, “Externalities, Environmental Policy, and Public Goods.”)

Many economists believe several aspects of health care involve externalities. For example, anyone vaccinated against a communicable disease not only protects herself or himself but also reduces the chances that people who have not been vaccinated will contract the disease. The positive externality from vaccinations causes a difference between the *private benefit* from being vaccinated and the *social benefit*. The *private benefit* is the benefit received by the consumer of a good or service. The *social benefit* is the total benefit from consuming a good or service, and it is equal to the private benefit plus any external benefit, such as the benefit to others from a reduced chance of getting a disease for which you have been vaccinated. Because of the positive externality, the social benefit of vaccinations is greater than the private benefit.

Figure 7.4 shows the market for vaccinations. If people receiving vaccinations could capture all the benefits, the demand curve would be D_2 , which represents the marginal social benefit. The actual demand curve is D_1 , however, which represents only the marginal private benefit received by people getting vaccinations. The efficient equilibrium would occur at price $P_{\text{Efficient}}$ and quantity $Q_{\text{Efficient}}$. At this equilibrium, economic surplus is maximized (see Chapter 4). The market equilibrium, at price P_{Market} and quantity Q_{Market} , will not be efficient because the demand curve is above the supply curve for production of the vaccinations between Q_{Market} and $Q_{\text{Efficient}}$. That is, the marginal benefit—including the external benefit—for producing these vaccinations is greater than the marginal cost. As a result, there is a deadweight loss equal to the area of the yellow triangle. Because of the positive externality, economic efficiency would be improved if more people were vaccinated.

Figure 7.4 assumes that the market for vaccinations is like the market for goods such as hamburgers, with consumers paying the full price of the vaccinations. In practice, people with health insurance pay a reduced price for vaccinations, and the government often provides further subsidies to the firms that produce vaccines. One reason for the government subsidies is to overcome the effects of the positive externality.

Externalities are important in health care markets, though economists and policymakers continue to debate the extent to which they require significant government involvement in health care.

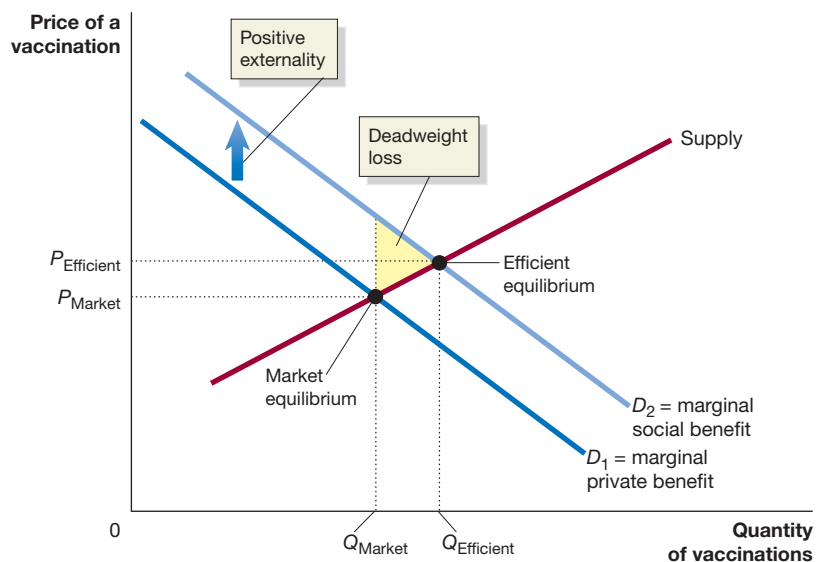

MyEconLab **Concept Check**

MyEconLab

Figure 7.4

The Effect of a Positive Externality on the Market for Vaccinations

People who do not get vaccinated still benefit from other people being vaccinated. As a result, the marginal social benefit from vaccinations is greater than the marginal private benefit to people being vaccinated. Because only the marginal private benefit is represented in the market demand curve D_1 , the quantity of vaccinations produced, Q_{Market} , is too low. If the market demand curve were D_2 instead of D_1 , the level of vaccinations would be $Q_{\text{Efficient}}$, which is the efficient level. At the market equilibrium of Q_{Market} , there is a deadweight loss equal to the area of the yellow triangle.

Should the Government Run the Health Care System?

Some members of Congress have proposed expanding the federal government's role in health care by adopting a system similar to the single-payer system used in Canada, under which the government would provide health care to all residents of the United States. What role the federal government should play in health care is a controversial public policy issue.

Economists categorize goods on the basis of whether they are *rival* and *excludable*. Rivalry occurs when one person consuming a unit of a good means no one else can consume it. If you consume a burrito from Chipotle Mexican Grill, for example, no one else can consume it. Excludability means that anyone who does not pay for a good cannot consume it. If you don't pay for a burrito, for example, Chipotle can exclude you from consuming it. A *public good* is both nonrival and nonexcludable. Public goods are often, although not always, supplied by a government rather than by private firms. The classic example of a public good is national defense. Your consuming national defense does not interfere with your neighbor consuming it, so consumption is nonrival. You also cannot be excluded from consuming it, whether you pay for it or not. No private firm would be willing to supply national defense because everyone can consume national defense without paying for it.

Is health care a public good that government should supply—or, at least, pay for? Is it a private good, like furniture, clothing, or computers, that private firms should supply and consumers should pay for without government aid? Should private firms supply most health care, subject to some government regulation? Economists differ in their answers to these questions because the delivery of health care involves a number of complex issues, but we can consider briefly some of the most important points. Because public goods must be both nonrival and nonexcludable, health care does not qualify as a public good under the usual definition. More than one person cannot simultaneously “consume” the same surgical operation performed by a particular doctor in a particular hospital. And someone who will not pay for an operation can be excluded from consuming it. (Most states require hospitals to treat patients who are too poor to pay for treatment, and many doctors will treat poor people at a reduced price. But health care does not fit the definition of a public good because there is nothing about health care that keeps people who do not pay for it from being excluded from consuming.)

However, there are aspects of the delivery of health care that have convinced some economists that government intervention is justified. For example, consuming certain types of health care generates positive externalities. Being vaccinated against a communicable disease, such as influenza or meningitis, reduces not only the chance that the person vaccinated will catch the disease but also the probability that an epidemic of the disease will occur. Therefore, the market may supply an inefficiently small quantity of vaccinations unless vaccinations receive a government subsidy.

Information problems can also be important in the market for private health insurance. Consumers who buy health insurance often know much more about the state of their health than do the companies selling health insurance. This information problem may raise costs to insurance companies when the pool of people being insured is small, making insurance companies less willing to offer health insurance to consumers the companies suspect may file too many claims. Economists debate how important information problems are in health care markets and whether government intervention is required to reduce them.

Many economists believe that market-based solutions are the best approach to improving the health care system. As we saw in Table 7.2 on page 283, the United States has a mixed record on health outcomes. The United States is, however, a world leader in innovation in medical technology and prescription drugs. The market-oriented approach to reforming health care starts with the goal of improving health care outcomes while preserving incentives for U.S. firms to continue with innovations in medical screening equipment, surgical procedures, and prescription drugs. Presently, markets are delivering inaccurate signals to consumers because when buying health

care, unlike when buying most other goods and services, consumers pay a price well below the true cost of providing the service. Under current tax laws, people do not pay taxes on health insurance benefits they receive from their employers, and this benefit encourages them to want generous coverage that reduces incentives to control costs. As we will discuss later in the chapter, market-based approaches to health care reform attempt to address these issues.

It remains an open question whether the U.S. health care system will continue to move toward greater government intervention, which is the approach adopted in most other countries, or whether market-based reforms will be implemented. Because health care is so important to consumers and because health care is an increasingly large part of the U.S. economy, the role of the government in the health care system is likely to be the subject of intense debate for some time to come.

7.4 The Debate over Health Care Policy in the United States

LEARNING OBJECTIVE: Explain the major issues involved in the debate over health care policy in the United States.

Shortly after taking office in January 2009, President Barack Obama proposed far-reaching changes in the U.S. health care system. The result was the Patient Protection and Affordable Care Act (ACA), which Congress passed in March 2010. The act was controversial, with every Republican member of Congress and 34 Democratic members voting against it. Since passage of the ACA, economists have vigorously debated its effects on health care and the economy. Next we explore the issue of rising health care costs, which played an important role in the health care debate, before discussing the details of the ACA and the debate over the legislation's effect.

The Rising Cost of Health Care

Figure 7.5 illustrates a key fact underlying the debate over health care policy in the United States: Health care's share of gross domestic product (GDP), which is the total value of output in the economy, is increasing. Panel (a) shows that spending on health care was less than 6 percent of GDP in 1965 but had risen to nearly 18 percent in 2015 and is projected to continue rising in future years. In other words, an increasing percentage of total production in the United States is being devoted to health care. Panel (b) shows increases in health care spending per person in the United States and 10 other high-income countries. Spending on health care has grown faster in the United States than in other countries.

Does it matter that spending on health care is an increasing share of total spending and output in the U.S. economy? The shares of different products in total spending change frequently. For instance, in the United States, the shares of spending on smartphones or 4K televisions were much greater in 2015 than in 2010. Spending on food as a share of total spending has been declining for decades. Economists interpret these changes as reflecting in part consumers' preferences: Consumers choose to spend relatively more of their incomes on smartphones and relatively less on food. As we have seen, though, most people pay for health care by relying on third-party payers, such as employer-provided health insurance or government-provided Medicare or Medicaid. Out-of-pocket spending, spending on health care that consumers pay out of their own incomes rather than through health insurance, has been declining.

Figure 7.6 shows that out-of-pocket spending on health care as a percentage of all spending on health care has fallen steadily since 1960. In 1960, 48 percent of all health care spending was out of pocket, while today only about 12 percent is. As a result, in recent years, consumers of health care have been directly paying for only a small fraction of the true cost of providing health care, with third-party payers picking up the remainder. As average incomes rise, consumers might be expected to spend a rising share of the increase on health care. But because consumers do not pay the full cost of increases in health care spending, they may not be willing to buy as much health care as they currently receive if they had to pay the full price.

MyEconLab Real-time data

Figure 7.5 Spending on Health Care around the World

Panel (a) shows that health care spending has been a rising percentage of GDP in the United States. Health care spending rose from less than 6 percent of GDP in 1965 to nearly 18 percent in 2015, and it is projected to rise to further in future years. (The projected increases are shown by the dotted line.) Panel (b) shows that health care spending per person

has been growing faster in the United States than in other high-income countries.

Because the federal and state governments in the United States pay for just over half of health care spending through Medicare, Medicaid, and other programs, increases in health care spending can cause problems for government budgets. The Medicare and Medicaid programs began in 1965. By 2015, spending on these programs had grown to 6 percent of GDP. That percentage is expected to double over the next 40 years unless health care costs begin to grow at a slower rate. Congress and the president have been struggling to find ways to pay for the projected increases in Medicare and Medicaid without severely cutting other federal spending or sharply raising taxes.

Are U.S. Firms Handicapped by Paying for Their Employees' Health Insurance?

Some members of Congress and some business leaders argue that the high cost of health care in the United States handicaps U.S. firms in competition with foreign firms. In many countries, firms do not purchase health insurance for their workers, as most large firms do in the United States. Do foreign firms in fact have an advantage over U.S. firms because of high U.S. health care costs? We can analyze this assertion using the demand and supply for labor.

The following figure illustrates the market for labor in a particular industry (for example, automobiles). The demand curve is downward sloping because the lower the wage, the larger the quantity of workers firms will demand. The supply curve is upward sloping because as the wage rises, more workers will want to work in this industry. (A fuller discussion of the labor market appears in Chapter 17, “The Markets for Labor and Other Factors of Production.”)

Equilibrium in this labor market occurs where the quantity of labor demanded equals the quantity of labor supplied. On the vertical axis, we measure the wage, so the graph shows the determination of the equilibrium wage. When choosing among jobs, however, workers don't just consider the wages firms offer; they also take into account *fringe benefits*, such as employer contributions to retirement accounts or employer-provided health insurance. It would therefore be more accurate to describe the intersection of the labor demand and labor supply curves as determining *the equilibrium compensation* rather than the equilibrium wage.

Suppose the United States moved to a health care system like Canada's, where the government pays for most health care from taxes. If labor markets determine equilibrium compensation, what would happen if firms no longer paid for their employees' health insurance? The Congressional Budget Office (CBO) undertakes studies of policy issues for Congress. In an overview of proposals for reforming health insurance in the United States, the CBO addressed this question:

Some observers have asserted that domestic producers that provide health insurance to their workers face higher costs for compensation than competitors based in countries where insurance is not employment based and that fundamental changes to the health insurance system could reduce or eliminate that disadvantage. However, such a cost reduction is unlikely to occur. . . . The equilibrium level of overall compensation in the economy is determined by the supply of and the demand for labor. Fringe benefits (such as health insurance) are just part of that compensation. Consequently, the

costs of fringe benefits are borne by workers largely in the form of lower cash wages than they would receive if no such benefits were provided by their employer. Replacing employment-based health care with a government-run system could reduce employers' payments for their workers' insurance, but the amount that they would have to pay in overall compensation would remain essentially unchanged.

To give an example, suppose a firm was paying its workers \$50,000 in wages and paying \$10,000 per worker for health insurance, thereby providing total compensation of \$60,000. If the government began paying all health care expenses, it might appear that the firm's labor costs would drop by \$10,000 per worker. But if the firm offered its employees only \$50,000 in wages as their total compensation, many would leave to work for other firms. The firm would have to pay its employees an additional \$10,000 in wages so that the total compensation it offered would be at the equilibrium level of \$60,000 for the industry. In other words, basic demand and supply analysis indicates that having firms rather than the government provide health insurance to workers changes the *composition* of the compensation the firms pay but does not change its level.

Explaining Increases in Health Care Spending

In this section, we briefly discuss some explanations for why health care's share of the U.S. economy has been continually increasing. We start by reviewing explanations that are sometimes offered by policymakers and journalists but that are unlikely to account for most of the increases in health care costs.

Factors That Do Not Explain Sustained Increases in Health Care Spending The two panels of Figure 7.5 on page 291 show that spending on health care has been growing faster than the economy as a whole for at least the past several decades. Explaining the rapid growth of health care spending requires identifying factors that have more than a one-time effect. For example, because the U.S. health care system relies on many independent hospitals, medical practices, and insurance companies, some observers argue that it generates more paperwork, duplication, and waste than systems in other countries. Even if this observation is correct, it cannot account for health care's rising share of GDP unless paperwork and waste are *increasing* year after year, which seems unlikely.

Unlike in most countries, it is relatively easy in the United States for patients who have been injured by medical errors to sue doctors and hospitals for damages. The Congressional Budget Office (CBO) estimates, though, that the payments to settle malpractice lawsuits plus the premiums doctors pay for malpractice insurance amount to less than 1 percent of health care costs. Other economists believe the CBO estimate is too low and that the costs of malpractice lawsuits, including the costs of unnecessary tests and procedures doctors order to avoid being sued, are as much as 7 percent of total health care costs. Still, these costs have not been significantly increasing over time.

Somewhere between 1 and 4 percent of health care costs are due to uninsured patients receiving treatments at hospital emergency rooms that could have been provided less expensively in doctors' offices. But once again, this cost has not been increasing rapidly enough to account for much of the increase in health care costs as a percentage of GDP.

"Cost Disease" in the Health Care Sector Some economists argue that health care suffers from a problem often encountered in service industries. In the sectors of the economy that produce goods, such as the manufacturing sector, *productivity*, or the

amount of output each worker can produce in a given period, increases steadily. These increases in productivity occur because over time firms provide workers with more machinery and equipment, including computers, with which to work, and because technological progress results in improvements in machinery and equipment and in other parts of the production process. As workers produce more goods, firms are able to pay them higher wages. In service-producing industries, increasing output per worker is more difficult. In medicine, MRI units, CT scanners, and other medical technology have improved diagnosis and treatment, but most medicine still requires a face-to-face meeting between a doctor and a patient. As wages rise in industries in which productivity is increasing rapidly, service industries in which productivity is increasing less rapidly must match these wage increases or lose workers. Because increases in wages are not offset by increases in productivity in service industries, the cost to firms of supplying services increases.

William Baumol of New York University has labeled the tendency for low productivity in service industries to lead to higher costs in those industries as “the cost disease of the service sector.” There is good reason to think that health care suffers from this cost disease because growth in labor productivity in health care has been less than half as fast as labor productivity growth in the economy as a whole. This slow growth in productivity can help explain why the cost of health care has been rising rapidly, thereby increasing health care’s share of total spending and output.

The Aging of the Population and Advances in Medical Technology As people age, they increase their spending on health care. Firms continue to develop new prescription drugs and medical equipment that typically have higher costs than the drugs and equipment they replace. The aging of the U.S. population and the introduction of higher-cost drugs and medical equipment interact to drive up spending on the federal government’s Medicare program and on health care generally. Many newly introduced drugs and diagnostic tools are used disproportionately by people over age 65. Partly as a result, health care spending on people over age 65 is six times greater than spending on people aged 18 to 24 and four times greater than on people aged 25 to 44. In 2015, more than 54 million people were enrolled in Medicare, and that number is expected to grow to 74 million by 2025. As we have seen, even in the absence of the development of new drugs and other medical technology, low rates of productivity in the health care sector could be expected to drive up costs. In fact, as Figure 7.7 illustrates, the CBO estimates that most of the increase in federal spending on Medicare and Medicaid benefits will be due to increases in the cost of providing health care rather than to the aging of the population. In the figure, “effect of excess cost growth” refers to the extent to which health care costs

Reasons for Rising Federal Spending on Medicare and Medicaid

per person grow faster than GDP per person. An aging population and increases in the cost of providing health care are key reasons why health care spending is an increasing percentage of GDP.

Distorted Economic Incentives As we noted earlier, some part of the increase in health care spending over the years represents consumers choosing to allocate more of their incomes to health care as their incomes rise. But as we have also seen, consumers usually pay less than the true cost of medical treatment because a third party—typically an insurance company or the government—often pays most of the bill. For example, consumers who have health insurance provided by their employers usually pay only a small amount—perhaps \$20—for a visit to a doctor’s office, when the true cost of the visit might be \$80 or \$90. The result is that consumers demand a larger quantity of health care services than they would if they paid a price that better represented the cost of providing the services.

Figure 7.8 illustrates this situation. If consumers paid the full price of medical services, their demand would be D_1 . The marginal benefit to consumers from medical services would equal the marginal cost of producing the services, and the equilibrium quantity would be at the efficient level $Q_{\text{Efficient}}$. However, because consumers pay only a fraction of the true cost of medical services, their demand increases to D_2 . In this equilibrium, the quantity of medical services produced increases to Q_{Market} , which is beyond the efficient level. The marginal cost of producing these additional units is greater than the marginal benefit consumers receive from them. As a result, there is a deadweight loss equal to the area of the yellow triangle. Doctors and other suppliers of medical services receive a price, P_{Market} , that is well above the price, P , paid by consumers. Note that the effect of a third-party payer is common to nearly all health care systems, whether the government provides health care directly, as is done in the United Kingdom, or whether many people have private health insurance, as in the United States.

In important ways, health insurance is different from other types of insurance. As we discussed earlier, the basic idea of insurance is that the financial risk of an unpredictable, high-cost event—a house fire or a serious car accident—is pooled among the many consumers who buy insurance. Health insurance, though, also typically covers many planned expenses, such as routine health checkups, annual physicals, and other low-cost events, such as treatment for minor illnesses. By disguising the true cost of these routine expenses, health insurance encourages overuse of health care services.

We discuss the role of economic incentives in health care further in the next section.

Recent Trends in Health Care

An article in the *New York Times* about recent trends in health care mentioned several developments:

1. An increase in the size of deductibles in employer-provided health care plans. For instance, the health plan at T. Cain Grocery supermarket chain mentioned in the chapter opener changed from having a premium of \$950 per month and a yearly deductible of \$500 to having a premium of \$400 per month and a yearly deductible of \$4,500.
2. An increase in the availability of lower-cost generic drugs.
3. A decline in patients being readmitted to hospitals after the Patient Protection and Affordable Care Act (ACA)

imposed penalties on hospitals that readmit too many patients.

- a. Use a graph of the market for medical services to show the effect of these trends. Be sure to explain any shifts in the demand curve or supply curve.
- b. Assuming that these are the only changes happening in the market for medical services, can we be certain whether they will result in an increase or decrease in the equilibrium price of medical services? In the equilibrium quantity of medical services? Briefly explain.

Solving the Problem

Step 1: Review the chapter material. This problem is about explaining changes in health care spending, so you may want to review the section “Explaining Increases in Health Care Spending,” which begins on page 293.

Step 2: Answer part (a) by drawing a graph of the market for medical services that shows the effect of the three trends and by explaining shifts in the curves. The first trend—higher deductibles—reduces moral hazard and adverse selection problems by increasing the quantity of medical services that employees purchase out-of-pocket. Employees are likely to visit doctors less frequently for minor illnesses such as colds. So, the demand curve for medical services will shift to the left. The second trend—greater availability of lower-cost drugs—reduces the cost of providing this type of medical service, which will shift the supply curve for medical services to the right. The third trend—a decline in the number of patients being readmitted to hospitals—should reduce the cost of hospitalizations because more patients are being successfully treated in a single stay. This trend will also cause the supply curve for medical services to shift to the right.

Your graph should look like the one below.

Step 3: Answer part (b) by explaining whether these trends will increase or decrease the equilibrium price and quantity of medical services. The graph in part (a) shows both the equilibrium price and the equilibrium quantity declining. We can be certain that the equilibrium price will decline because the shift of the demand curve to the left and the shift of the supply curve to the right both cause the equilibrium price to decline. However, we can't be certain that the equilibrium quantity will decline because the effect of the supply curve shifting to the right is to make the equilibrium quantity *increase*. Whether the equilibrium quantity declines depends on whether demand shifts more or less than supply shifts. Although two of the trends listed affect supply and only one affects demand, we do not know the size of the shift that results from any of the trends, so we can't tell with certainty what the effect will be on the equilibrium quantity.

Extra Credit: The cost of medical care has continued to increase. In 2015, however, economists were analyzing the reasons for a slowdown in the *rate* of that increase. The trends mentioned in this problem were among the likely factors. The quantity of medical services continued to increase, at least partly as a result of the effects of the Affordable Care Act. The act provides subsidies to buy health insurance for people whose incomes fall below a certain level and has expanded the Medicaid system, thereby increasing the demand for health care among low-income people.

The Continuing Debate over Health Care Policy

As we have seen, the United States has been unusual among high-income countries in relying on private health insurance, usually purchased through employers or the new health insurance marketplaces, to provide health care coverage to the majority of the population. Most other high-income countries either provide health care directly, as the United Kingdom does, through government-owned hospitals and government-employed doctors, or provide health insurance to all residents, as Canada does, without directly employing doctors or owning hospitals. There have been several attempts to reorganize the U.S. health care system to make it more like the systems in other countries. In 1945, President Harry Truman proposed a plan for *national health insurance* under which anyone could purchase health insurance from the federal government. The health insurance would have covered treatment received from doctors and hospitals that agreed to enroll in the system. Congress declined to enact the plan. In 1993, President Bill Clinton proposed a health care plan intended to provide universal coverage. While somewhat complex, the plan was based on requiring most businesses to provide health insurance to their employees and new government-sponsored health alliances that would ensure coverage for anyone who otherwise would not have health insurance. After a prolonged political debate, Congress chose not to enact President Clinton's plan.

The Patient Protection and Affordable Care Act In 2009, President Barack Obama proposed health care legislation that after much debate and significant changes was signed into law as the **Patient Protection and Affordable Care Act (ACA)** in March 2010. The act was long and complex, taking up over 20,000 pages and touching nearly every aspect of health care in the United States. Here is a summary of only the main provisions of the act:

- **Individual mandate.** The act requires that, with limited exceptions, every resident of the United States have health insurance that meets certain basic requirements. Individuals who do not acquire health insurance are subject to a fine. In 2016 the fine was \$695 or 2.5 percent of income, whichever was greater. (The fine will rise with

Patient Protection and Affordable Care Act (ACA) Health care reform legislation passed by Congress and signed by President Barack Obama in 2010.

inflation in future years). For example, in 2016 an adult with an income of \$40,000 per year paid a fine of \$1,000 if he or she did not buy health insurance.

- **State health insurance marketplaces.** Each state must establish a marketplace called an Affordable Insurance Exchange. Separate marketplaces were established for individuals and small businesses with fewer than 50 employees. The marketplaces offer health insurance policies that meet certain specified requirements. Although the marketplaces were intended to be run by a state government agency or a nonprofit firm, a number of states decided to allow the federal government to run the marketplace in their state. Private insurance companies compete by offering policies on the marketplaces to individuals and small businesses. Low-income individuals and small businesses with 25 or fewer employees are eligible for tax credits to offset the costs of buying health insurance. The purpose of the marketplaces is to allow greater risk pooling and lower administrative costs than had existed in the market for health insurance policies sold to individuals or small businesses. If successful, greater risk pooling and lower administrative costs will make it possible for individuals and small businesses to buy policies with lower premiums than had been available.
- **Employer mandate.** Every firm with more than 200 full-time employees must offer health insurance to its employees and must automatically enroll them in the plan. Firms with 50 or more full-time employees must offer health insurance or pay a fee of \$3,000 to the federal government for every employee who receives a tax credit from the federal government for obtaining health insurance through a health insurance marketplace. A worker is a full-time employee if he or she works at least 30 hours per week.
- **Regulation of health insurance.** Insurance companies are required to participate in a high-risk pool that will insure individuals with preexisting medical conditions who have been unable to buy health insurance for at least six months. All individual and group policies must provide coverage for dependent children up to age 26. Lifetime dollar maximums on coverage are prohibited. Limits are also placed on the size of deductibles and on the waiting period before coverage becomes effective.
- **Changes to Medicare and Medicaid.** Eligibility for Medicaid was originally expanded to persons with incomes up to 138 percent of the federal poverty line, although a 2012 Supreme Court decision resulted in the states being allowed to opt out of this requirement. In an attempt to control increases in health care costs, the Independent Payment Advisory Board (IPAB) was established and given the power to reduce Medicare payments for prescription drugs and the use of diagnostic equipment and other technology if Medicare spending exceeds certain levels. Some Medicare reimbursements to hospitals and doctors were reduced.
- **Taxes.** Several new taxes help fund the program. Workers earning more than \$200,000 pay higher Medicare payroll taxes, and people who earn more than \$200,000 pay a new 3.8 percent tax on their investment income. Beginning in 2018, a tax is scheduled to be imposed on employer-provided health insurance plans that have a value above \$10,200 for an individual or \$27,500 for a family—so-called Cadillac plans. Pharmaceutical firms, health insurance firms, and firms producing medical devices also pay new taxes.

The ACA is scheduled to be fully implemented by 2019, at which point more than 30 million additional individuals are expected to have health care coverage. The CBO estimates that the law will increase federal government spending by about \$2.0 trillion over the period 2016 to 2025. Increases in taxes and fees will reduce the net increase in federal spending resulting from the act to about \$1.4 trillion.

The Debate over the ACA Any law as far-reaching and complex as the ACA is bound to draw criticism. The congressional debate over the law was highly partisan, with every Republican ultimately voting against it and most Democrats voting in favor

of it. Critics of the act can be divided into two broad groups: those who argue that health care reform should involve a greater movement toward a system similar to the British, Canadian, and Japanese systems and those who argue that health care reform should include more market-based changes.

As we discussed in the previous section, some economists and policymakers believe that information problems and externalities in the market for health care are sufficiently large that the government should either provide health care directly through government-owned hospitals and government-employed doctors or pay for health care through national health insurance, sometimes called a *single-payer system*. Although the ACA significantly increased the federal government's involvement in the health care system, it stopped short of the degree of government involvement that exists in Canada, Japan, or the United Kingdom. Those in favor of moving toward greater government involvement typically argue that doing so would reduce the paperwork and waste caused by the current system. They argue that the current Medicare system—which is essentially a single-payer system for people over age 65—has proved to have lower administrative costs than have private health insurance companies. Supporters of greater government involvement in the health care system have also argued that the Canadian and British systems have had lower levels of health care spending per person and lower rates of increase in total health care spending, while providing good health outcomes.

Market-based reforms involve changing the market for health care so that it becomes more like the markets for other goods and services. As in other markets, the prices consumers pay and suppliers receive would do a better job of conveying information on consumer demand and supplier costs. The expectation is that increased competition among doctors, hospitals, pharmaceutical companies, and other providers of health care would reduce costs and increase economic efficiency. Economists who support market-based reforms as the best way to improve the health care system were disappointed that the ACA did not adopt this approach. Currently, markets are delivering inaccurate signals to consumers because when buying health care, unlike when buying most other goods and services, consumers pay a price well below the true cost of providing the service.

How Much Is That MRI Scan?

Magnetic resonance imaging (MRI) units play an important role in modern medicine. First introduced in the early 1980s, they allow doctors to see inside the body's soft tissues to identify tumors, torn muscles, and other medical problems.

As we noted in Section 7.2, MRI units are more widely available in the United States than in most other countries. We would normally expect that when a product is widely available, competition among firms results in the price of the product being about the same everywhere. Customers would not buy a best-selling book from Amazon.com if the price was 50 percent higher there than on BarnesandNoble.com.

Does competition equalize the prices of medical services? The evidence indicates that it doesn't. The exact services each hospital or clinic offers are difficult to discover, which makes it difficult for consumers to compare prices. The data in the table below indicate that the prices of abdominal MRI scans vary widely. In most cities in the United States, the most expensive MRI scan has a price that is more than double the least expensive scan. And prices for MRI scans also vary widely across cities. Two reporters looking at prices for shoulder MRI scans in Pensacola, Florida, found that Sacred Heart Hospital was charging \$800 for a shoulder MRI scan, while Pensacola Open MRI & Imaging, a private firm located less than one mile away, was charging \$450 for the same scan. Pensacola Open MRI & Imaging was actually using newer MRI units that give higher-resolution images, so it was charging less for a better service.

City	Highest Price	Lowest Price	Difference
Houston, Texas	\$4,800	\$675	\$4,125
Baton Rouge, Louisiana	4,400	600	3,800
Chicago, Illinois	4,200	450	3,750
Atlanta, Georgia	4,400	700	3,700
Omaha, Nebraska	4,100	600	3,500
Lexington, Kentucky	4,000	550	3,450
Charlotte, North Carolina	3,500	600	2,900
Orlando, Florida	2,475	650	1,825
San Francisco, California	2,400	650	1,750
New York, New York	2,175	800	1,375

How can some providers of medical services charge hundreds or thousands of dollars more than competitors and remain in business? The answer is that most patients are not concerned about prices because they either do not pay them or they pay only a small fraction of them. Patients typically rely on doctors to refer them to a facility for an MRI scan or other procedure and make little or no effort to determine the price the facility charges. A goal of market-based reforms of the health care system is to give patients an incentive to pay more attention to the prices of medical services.

Your Turn: Test your understanding by doing related problem 4.13 on page 306 at the end of this chapter.

Supporters of market-based reforms note that employees have to pay federal income and payroll taxes on the wages their employers pay them, but in most circumstances they do not pay taxes on the value of the health insurance their employers provide them. This feature of the tax laws encourages employees to want generous health care coverage; in fact, if offered the choice between a \$1,000 salary increase or increased health care coverage that was worth \$1,000, many people would choose the increased health care coverage because it would be tax free (although someone who was young and healthy and did not expect to have medical bills would probably choose the increase in salary). The size of this tax break is quite substantial—more than \$250 billion in 2015. But individuals typically get no tax break when buying an individual health insurance policy or when they spend money on health care out of pocket.¹

Some economists have proposed making the tax treatment of employer-provided health insurance the same as the tax treatment of individually purchased health insurance and out-of-pocket health care spending. They argue that this change could, potentially, significantly reduce spending on health care without reducing the effectiveness of the health care received. Such tax law changes would make it more likely that employer-provided health insurance would focus on large medical bills—such as those resulting from hospitalizations—while consumers would pay prices closer to the costs of providing routine medical care. John Cogan of the Hoover Institution, Glenn Hubbard of Columbia University, and Daniel Kessler of Stanford University estimate that repealing the tax preference for employer-provided health insurance would reduce spending by people enrolled in these programs by 33 percent.

¹ Individuals receive a deduction on their federal income tax only if their medical expenses are greater than 10 percent of their income. Only a relatively small number of individuals have expenses high enough to use that deduction.

Currently, the U.S. health care system is a world leader in innovation in medical technology and prescription drugs. About two-thirds of pharmaceutical patents are issued to U.S. firms and about two-thirds of research on new medicines is carried out in the United States. One goal of market-based reforms would be to ensure that U.S. firms continue with innovations in medical screening equipment, surgical procedures, and prescription drugs. Executives of U.S. pharmaceutical firms have voiced concern over whether aspects of the ACA will affect their ability to profitably bring new prescription drugs to market. In particular, managers at these firms worry that the new Independent Payment Advisory Board (IPAB) might reduce the payments Medicare would make for new prescription drugs.

Both critics of the ACA who favor greater government involvement in health care and those who favor market reforms raise questions about the act's individual mandate. The individual mandate requires every U.S. resident to have health insurance. The mandate was considered necessary because otherwise healthy people might avoid buying insurance until they become ill. Because insurance companies would not be allowed to deny coverage for preexisting conditions, they would end up paying large medical bills for people who had not been paying premiums to support the system while they were healthy. People who do not buy insurance are subject to fines under the act, but there were questions about how effective the fines would be in pushing people to buy insurance. In 2015, several million people paid the fine rather than buy insurance.

Economics in Your Life

Is Your Take-Home Pay Affected by What Your Employer Spends on Your Health Insurance?

At the beginning of this chapter, we asked you to think about this question: Your paycheck doesn't show the amount your employer pays on your behalf for health insurance, but does that amount affect your take-home pay? The *Making the Connection* on page 292 shows that the equilibrium compensation that workers receive in labor markets is made up partly of wages and partly of fringe benefits such as health insurance. So, while the amount that a firm pays on your behalf for health insurance may not affect your total compensation, it will affect the amount of your take-home pay. For a given level of compensation, the more a firm pays for your health insurance, the less it will pay you in wages. A related question is why a firm would buy health insurance for you rather than increase your wages by the same amount and let you buy your own insurance. We have seen that there are two important reasons so many people receive health insurance from their employers: (1) The wage an employer pays you is taxable income to you, but the money an employer spends to buy health insurance for you is not taxable; and (2) insurance companies are typically willing to charge lower premiums for group insurance, particularly to large employers, because risk pooling is improved and adverse selection and moral hazard problems are lower than with individual policies.

Conclusion

In this chapter, we have seen that economic analysis can provide important insights into the market for health care. As with many other policy issues, though, economic analysis can help inform the debate but cannot resolve it. Because health care is so important to consumers and health care services are such a large part of the U.S. economy, the role of the government in the health care system is likely to be the subject of intense debate for years to come.

The Improving Health of People in the United States, pages 276–278

LEARNING OBJECTIVE: Discuss trends in U.S. health over time.

Summary

Health care refers to goods and services, such as prescription drugs and consultations with a doctor, that are intended to maintain or improve health. Over time, the health of people in most countries has improved. In the United States, as a result of improving health, life expectancy has increased, death rates have decreased, infant mortality has decreased, and the average person has become taller.

Review Questions

- 1.1 Briefly discuss the most important differences between the market for health care and the markets for other goods and services.
- 1.2 List the reasons for the long-term improvements in the health of Americans. How can developing countries benefit from this experience?
- 1.3 How can improvements in health increase a country's total income? How can increases in a country's total income improve health?

Problems and Applications

- 1.4 Briefly explain why you can see the existence of a connection between health conditions and income, that is, production. What are the reasons for an increase in income and production of a country following improvements in the health of its population?
- 1.5 The widespread realization in the late nineteenth century that bacteria causes diseases helped lead to a public health movement. This movement eventually brought sewers, clean drinking water, and garbage removal to all U.S. cities. What effect did the public health movement in the United States in the late nineteenth and early twentieth centuries have on the country's production possibilities frontier?
- 1.6 Between 1830 and 1890, the height of the average adult male in the United States declined by about 2 inches at the same time that average incomes more than tripled. Did the standard of living in the United States increase during this period? What insight into the health and well-being of the U.S. population might the decline in height provide? Briefly explain.

7.2

Health Care around the World, pages 278–284

LEARNING OBJECTIVE: Compare the health care systems and health care outcomes in the United States and other countries.

Summary

Health insurance is a contract under which a buyer agrees to make payments, or premiums, in exchange for the provider agreeing to pay some or all of the buyer's medical bills. A majority of people in the United States live in households that have private health insurance, which they typically obtain through an employer. Other people have health insurance through the Veteran's Administration or the Medicare and Medicaid programs. In 2014, about 10 percent of people in the United States lacked health insurance. Many health insurance plans operate on a **fee-for-service** basis, under which doctors and hospitals receive a payment for each service they provide. Most countries outside the United States have greater government involvement in their health care systems. Canada has a **single-payer health care system**, in which the government provides national health

insurance to all Canadian residents. In the United Kingdom, the government owns most hospitals and employs most doctors, so the health care system is referred to as **socialized medicine**. The United States spends more per person on health care than do other high-income countries. The United States has lower life expectancy, higher infant mortality, and a greater incidence of obesity than do other high-income countries. The United States has more medical technology per person and has lower mortality rates for people diagnosed with cancer than do other high-income countries. Data and other problems make it difficult to compare health care outcomes across countries.

 - a. Demographic decline
 - b. High rate of suicides
 - c. Planning a war
 - d. Emigration of doctors and nurses
- 2.9 The healthcare system in Poland is heavily criticized for its inadequacies, such as long-waiting lists for specialist treatment, corruption, nepotism, and lack of sufficient quality control. How could the efficiency of its health care system be improved?

7.3

Information Problems and Externalities in the Market for Health Care, pages 284–290

LEARNING OBJECTIVE: Discuss how information problems and externalities affect the market for health care.

Summary

The market for health care is affected by the problem of **asymmetric information**, which occurs when one party to an economic transaction has less information than the other party. **Adverse selection**, the situation in which one party to a transaction takes advantage of knowing more than the other party to the transaction, is a problem for firms selling health insurance policies because it results in people who are less healthy being more likely to buy insurance than people who are healthier. **Moral hazard**, actions people take after they have entered into a transaction that make the other party to the transaction worse off, is also a problem for insurance companies because once people have health insurance, they are likely to make more visits to their doctors and in other

ways increase their use of medical services. Moral hazard can also involve a **principal-agent problem**, in which doctors may order more lab tests, MRI scans, and other procedures than they would if their patients lacked health insurance. Insurance companies use deductibles and copayments to reduce the problems of adverse selection and moral hazard. There may be externalities involved with medicine and health care because, for example, people who are vaccinated against influenza or other diseases may not receive all of the benefits from having been vaccinated, and people who become obese may not bear all of the costs from their obesity.

The Debate over Health Care Policy in the United States, pages 290–301

LEARNING OBJECTIVE: Explain the major issues involved in the debate over health care policy in the United States.

Summary

In 2010, Congress passed the **Patient Protection and Affordable Care Act (ACA)**, which significantly reorganized the U.S. health care system. Spending on health care in the United States has been growing rapidly as a percentage of GDP, and spending per person on health care has been growing more rapidly than in other high-income countries. Third-party payers, such as employer-provided health insurance and the Medicare and Medicaid programs, have financed an increasing fraction of health care spending, while out-of-pocket payments have sharply declined as a fraction of total health care spending. Several explanations have been offered for the rapid increase in health care spending in the United States: Slow rates of growth of labor productivity in health care may be driving up costs, the U.S. population is becoming older, medical technology and new prescription drugs have higher costs, and the tax system and the reliance on third-party payers have distorted the economic incentives of consumers and suppliers of health care. The ACA has several important provisions: (1) an individual mandate that requires every resident of the United States to obtain health insurance or be fined; (2) the establishment of health exchanges that will be run by the state or federal governments and provide a means for individuals and small businesses to purchase health insurance; (3) an employer mandate that requires every firm with more than 200 employees to offer health insurance to them; (4) increased regulation of health insurance companies; (5) expansion of eligibility for Medicaid and the establishment of the Independent Payment Advisory Board (IPAB), which has the power to reduce Medicare payments for prescription drugs and for the use of diagnostic equipment and other technology if Medicare spending exceeds certain levels; and (6) increased taxes on people with incomes above \$200,000. Some critics of the ACA argue that it does not go far enough in increasing government involvement in the health care system, while other critics argue that health care reform should rely more heavily on **market-based reforms**, which involve changing the market for health care so that it becomes more like the markets for other goods and services.

- 4.6 In 2013, a column in the *Forbes*, “Is Big Pharma Addicted To Fraud?” informed that the Chinese authorities said they were investigating GlaxoSmithKline and other pharmaceutical companies for bribing doctors, hospitals, and government officials to buy and prescribe their drugs. The article stated that Glaxo was accused of using a Shanghai travel agency to funnel at least \$489 million in bribes. Gifts, sponsoring trips to conferences in exotic destinations, generous rewards for completing surveys, and contacts between the representatives of pharmaceutical companies and doctors give rise to a lot of ethical doubts, especially when considering the money at stake. In Poland, pharmacists are obliged by law to inform their customers of the possibility of buying a cheaper medicine than the one prescribed, if there is a cheaper substitute that has the same composition as the original drug. Why is the lobbying of pharma companies a negative phenomenon? Are there any ways to control and stop it?

- 4.7 Improvements in technology usually result in lower costs of production or new and improved consumer goods and services. Assume that an improvement in medical technology results in an increase in life expectancy for people 65 years of age and older. How would this technological advance be likely to affect expenditures on health care?
- 4.8 Some economists and policymakers have argued that one way to control federal government spending on Medicare is to have a board of experts decide whether new medical technologies are worth their higher costs. If the board decides that they are *not* worth the costs, Medicare would not pay for them. Other economists and policymakers argue that the costs to beneficiaries should more closely represent the costs of providing medical services. This result might be attained by raising premiums, deductibles, and copayments or by “means testing,” which would limit the Medicare benefits that high-income individuals receive. Political columnist David Brooks has summarized these two ways to restrain the growth of spending on Medicare: “From the top, a body of experts can be empowered to make rationing decisions. ... Alternatively, at the bottom, costs can be shifted to beneficiaries with premium supports to help them handle the burden.”
 - a. What are “rationing decisions”? How would these decisions restrain the growth of Medicare spending?

- b. How would shifting the costs of Medicare to beneficiaries restrain the growth of Medicare spending? What does Brooks mean by “premium supports”?
- c. Should Congress and the president be concerned about the growth of Medicare spending? If so, which of these approaches should they adopt, or is there a third approach that might be better? (Note: This last question is normative and has no definitive answer. It is intended to lead you to consider possible approaches to the Medicare program.)

- 4.9** Article 68 of the Constitution of Poland states that (...) Equal access to health care services, financed from public funds, shall be ensured by public authorities to citizens, irrespective of their material situation.

Health care in Poland is delivered through a publicly funded health care system, which is free for all the citizens who are insured. Nevertheless, in reality the system is far from being efficient. One of the main problems is long queues for surgeries in public hospitals. Some patients choose to pay for surgeries in a private clinic. Others bribe the doctors employed in a public institution to help them “cut into” the line. The bribe is seldom offered in the form of a traditional envelope. Patients prefer to pay a market fee for a consultation with the doctor in a private clinic where they work after their duty in the hospital. Discuss the possible solutions.

Is Twitter the Next Facebook?

Most people today have trouble imagining a world without Facebook, Twitter, Snapchat, and Instagram. All four of these social networking applications (“apps”) are businesses that started small but have since grown rapidly. To finance that growth, they needed to raise funds. Some businesses raise funds by borrowing from banks. Once firms grow large enough, they can become *public firms* and sell stocks and bonds to investors in financial markets, such as the New York Stock Exchange. Firms that do not sell stock are called *private firms*. Both Facebook and Twitter have made the transition to being public firms. The founders of Snapchat, the mobile photo-sharing app, took a different approach: In 2012, they sold their company to Facebook for \$1 billion. In the summer of 2015, Instagram, which allows people to share photos and 15-second videos, was still a private company. It was relying on investments from venture capital firms, which provide funds to private companies in exchange for part ownership.

A major decision for a successful social media startup is whether to remain a private firm, to become a public firm, or to sell itself to a larger firm as Snapchat did. Becoming a public firm provides access to greater financing but can also have drawbacks. From the time Mark Zuckerberg started Facebook in 2004 as a sophomore in college until the company went public in 2012, he was the unquestioned leader of the company. But

buyers of Facebook’s stock have partial ownership of the firm and a claim on its profits and can question Zuckerberg’s decisions. Twitter became a public firm in 2013.

Stockholders want to invest in companies that can earn a profit. During its first year as a public company, Facebook struggled to meet the expectations of its investors. Eventually, Facebook was able to find a better way to target advertising on its app, and its stock more than doubled from its initial price in 2012 of \$38 per share.

Twitter, however, found life as a public company to be more challenging. By 2015, it had more than 300 million active users and had become an important part of many people’s lives. But advertisers who provided most of the company’s revenue weren’t convinced that advertising on the site was actually effective.

As we will see in this chapter, the ability of firms such as Twitter and Facebook to raise funds in financial markets is crucial to the health of the economy. Financial markets are also an important source of investment opportunities to households as they accumulate savings to buy houses, pay for college, and prepare for retirement.

Economics in Your Life

Would You Pay to Use Facebook or Twitter?

You can use Facebook or Twitter for free—or can you? Social media apps don’t charge you directly; instead they earn their revenue primarily by displaying ads as you use the app. Most sites collect data about your Web searches and browsing habits and then display ads for products they think you might buy. But many people see targeted ads as an invasion of their privacy. Some of these people would be willing to pay to use these apps if they could do so without having to see advertisements. Would you be willing to pay to use social media apps? Do you think other users would be willing to pay enough that firms could rely on that source of revenue? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 327** at the end of this chapter.

In this chapter, we look at firms: how they are organized, how they raise funds, and the information they provide to investors. As we have discussed in earlier chapters, firms in a market system are responsible for organizing the factors of production to produce goods and services. Entrepreneurs start firms to earn a profit by offering a good or service. To succeed, entrepreneurs must meet consumers' wants by producing new or better goods and services or by finding ways to produce existing goods and services at a lower cost so that they can be sold at a lower price. Entrepreneurs also need access to sufficient funds, and they must be able to efficiently organize production. As the typical firm in many industries has become larger over the past 100 years, the task of efficiently organizing production has become more difficult. In the final section of this chapter, we look at problems of *corporate governance* that have occurred in recent years. We also look at the steps firms and the government have taken to avoid similar problems in the future.

8.1 Types of Firms

LEARNING OBJECTIVE: Categorize the major types of firms in the United States.

In studying a market economy, it is important to understand the basics of how firms operate. In the United States, there are three main categories of firms:

Sole proprietorship A firm owned by a single individual and not organized as a corporation.

Partnership A firm owned jointly by two or more persons and not organized as a corporation.

Corporation A legal form of business that provides owners with protection from losing more than their investment should the business fail.

1. A **sole proprietorship** is a firm owned by a single individual. Although most sole proprietorships are small, some employ many workers and earn large profits.
2. A **partnership** is a firm owned jointly by two or more—sometimes many—persons. Most law and accounting firms are partnerships. Some of them can be quite large. For instance, in 2015, the Baker & McKenzie law firm based in Chicago had 1,400 partners.
3. A **corporation** is a legal form of business that provides owners with protection from losing more than their investment in the firm should the business fail. Most large firms are organized as corporations.

Asset Anything of value owned by a person or a firm.

Who Is Liable? Limited and Unlimited Liability

A key distinction among the three types of firms is that the owners of sole proprietorships and partnerships have unlimited liability, which means that there is no legal distinction between the personal assets of the owners of the firm and the assets of the firm. An **asset** is anything of value owned by a person or a firm. If a sole proprietorship or a partnership owes a lot of money to the firm's suppliers or employees, the suppliers and employees have a legal right to sue the firm for payment, even if in order to pay their debts, the firm's owners have to sell some of their personal assets, such as stocks or bonds. In other words, with sole proprietorships and partnerships, the owners are not legally distinct from the firms they own.

It may only seem fair that the owners of a firm be responsible for the firm's debts. But in the early 1800s, many state legislatures in the United States realized that unlimited liability was a significant problem for any firm that was attempting to raise funds from large numbers of investors. An investor might be interested in making a relatively small investment in a firm but be unwilling to become a partner in the firm for fear of placing at risk all of his or her personal assets if the firm were to fail. To get around this problem, state legislatures began to pass *general incorporation laws*, which allowed firms to more easily be organized as corporations. Under the corporate form of business, the owners of a firm have **limited liability**, which means that if the firm fails, the owners can never lose more than the amount they have invested in the firm. The personal assets of the owners of the firm are not affected by the failure of the firm. In fact, in the eyes of the law, a corporation is a legal "person," separate from its owners. Limited liability has made it possible for corporations to raise funds by issuing shares of stock to large numbers of investors. For example, if you buy a share of Twitter stock, you are a part owner of the firm, but if Twitter were to go bankrupt, you would not be

Organizing a firm as a corporation also has some disadvantages. In the United States, corporate profits are taxed twice—once at the corporate level and again when investors in the firm receive a share of the firm's profits. Corporations generally are larger than sole proprietorships and partnerships and are therefore more difficult to organize and run. Table 8.1 reviews the advantages and disadvantages of the three types of business organizations.

Corporations Earn the Majority of Revenue and Profits

Figure 8.1 gives basic statistics on the three types of business organizations. Panel (a) shows that almost three-quarters of all firms are sole proprietorships. Panels (b) and (c) show that although only 18 percent of all firms are corporations, they account for a majority of the revenue and profits earned by all firms. *Profit* is the difference between revenue and the total cost to a firm of producing the goods and services it offers for sale.

There are more than 5.8 million corporations in the United States, but only 37,000 have annual revenues of more than \$50 million. We can think of these 37,000 firms—including Apple, McDonald's, and Facebook—as representing “big business.” These large firms earn more than 80 percent of the total profits of all corporations in the United States.

Why Are Fewer Young People Starting Businesses?

We have seen that although a large majority of all firms are sole proprietorships, they account for only a small fraction of the total revenue and profit earned by all firms. In fact, more than 70 percent of people work at firms that have 50 or more employees. Does this mean that small businesses are not important to the U.S. economy?

On the contrary, most economists would argue that small businesses are vital to the health of the economy. Starting a small firm provides an entrepreneur with a vehicle for bringing a new product or process to market. During the late nineteenth and early twentieth centuries, Thomas Edison, Henry Ford, and the Wright Brothers were all responsible for introducing important products shortly after starting what were initially very small firms. In more recent years, Bill Gates, Steve Jobs, Michael Dell, and Mark Zuckerberg decided that the best way to develop their ideas was by founding Microsoft, Apple, Dell Computer, and Facebook rather than by choosing to work for large corporations.

In most years, more than 400,000 new firms open in the United States, and, of these, more than 95 percent employ fewer than 20 workers. In a typical year, new small firms create 3.3 million jobs. Forty percent of all new jobs are created by small firms, and in some years more than half are. Looking just at newly started firms, more than 85 percent of jobs created are created by small firms.

Because of the importance of small firms, some economists and policymakers have been concerned by a slowdown in recent years in the number of firms started. As the graph below shows, in the late 1970s, more than 15 percent of all firms were less than a year old. In recent years, only about 8 percent were. In absolute numbers, in recent years business startups have been running about 25 percent below the levels of just 10 years ago. The decline in starting new businesses is not concentrated in one industry or geographic area but has occurred across industries, including the information and high-tech sectors, and in most states and cities.

The decline in starting new firms has been particularly large among people under the age of 35. At first, this trend may seem surprising because of the publicity received by high-tech startups such as Twitter, Facebook, Uber, and Airbnb, all of which were started by young entrepreneurs. But while in the 1990s about one-third of all new firms were started by people younger than 35, today fewer than one-quarter are.

Source: U.S. Census Bureau, "Business Dynamics Statistics, Firm Characteristics Data Tables," June 2015.

Economists have not come to a consensus on the reasons for the decline in business startups. Some economists believe that despite the publicity received by innovative high-tech firms, the overall U.S. economy is experiencing a slowdown in technological progress. With fewer new technologies being introduced, there are fewer opportunities to start new firms selling new goods and services. Some economists believe that an increase in government regulations has raised the costs of starting and running a small business. For example, state and local governments have imposed licensing requirements on many occupations. According to one study, while at one time only 5 percent of workers were in an occupation that required a license, today more than 20 percent are. Slowing population growth may also have reduced the opportunities to start new businesses.

Whatever the explanation, many economists and policymakers worry that without an increase in young entrepreneurs starting new firms, the U.S. economy will become less dynamic and less able to sustain high rates of economic growth.

MyEconLab Study Plan

The Structure of Corporations and the Principal–Agent Problem

Large corporations account for a majority of sales and profits in the economy, so it is important to know how they are managed. Most large corporations have a similar management structure. The way in which a corporation is structured and the effect that structure has on the corporation’s behavior is referred to as **corporate governance**.

Corporations are legally owned by their *shareholders*, the owners of the corporation’s stock. Unlike with a sole proprietorship, a corporation’s shareholders own the firm but don’t directly manage it. Instead, they elect a *board of directors* to represent their interests. The board of directors appoints a *chief executive officer* (CEO) to run the day-to-day operations of the corporation. Sometimes the board of directors also appoints other members of *top management*, such as the *chief financial officer* (CFO). At other times, the CEO appoints other members of top management. Members of top management—sometimes called C-suite executives—including the CEO and CFO, often serve on the board of directors. They are called *inside directors*. Members of the board of directors who do not have a direct management role in the firm are called *outside directors*. The outside directors are intended to act as a check on the decisions of top managers.

Unlike the owners of family businesses, the top management of a large corporation does not generally own a large share of the firm’s stock, so large corporations have a **separation of ownership from control**. Although the shareholders actually own the firm, the top management controls the firm’s day-to-day operations. Because top managers own only a small percentage of the firm’s stock, they may decrease the firm’s profits by spending money to purchase private jets or schedule management meetings at luxurious resorts. Economists refer to the conflict between the interests of shareholders and the interests of the top management as a **principal–agent problem**.¹ This problem occurs when agents—in this case, a firm’s top management—pursue their own interests rather than the interests of the principal who hired them—in this case, the shareholders of the corporation. Because the outside directors are not involved with the daily operations of the firm, they may have difficulty deciding whether the actions taken by

Principal–agent problem A problem caused by an agent pursuing his own interests rather than the interests of the principal who hired him.

¹ In Chapter 7, we saw that the principal–agent problem arises from moral hazard that can occur because of asymmetric information. In this case, the asymmetric information involves top managers knowing more about how the firm is actually run than do the firm’s shareholders.

MyEconLab Concept Check

top managers really are in the best interests of shareholders. To reduce the effect of the principal–agent problem, many boards of directors in the 1990s began to tie the salaries of top managers to the profits of the firm or to the price of the firm’s stock. They hoped this step would give top managers an incentive to make the firm as profitable as possible, thereby benefiting its shareholders. Sometimes, though, top managers act in ways that increase the profits of the firm in the short run—and the salaries and bonuses of the top managers—but actually reduce the profits of the firm in the long run.

8.2 How Firms Raise Funds

LEARNING OBJECTIVE: Explain how firms raise the funds they need to operate and expand.

Owners and managers of firms try to earn a profit. To succeed, a firm must raise funds to pay for its operations, including paying its employees and buying or renting computers and other machinery and equipment. In fact, a central challenge for anyone running a firm, whether that person is a sole proprietor or a top manager of a large corporation, is raising the funds needed to operate and expand the business. Suppose you develop a new social networking app, and you decide to start a business using \$100,000 you have saved in a bank. You use the \$100,000 to rent an office for your firm, buy computers, and pay other startup expenses. Your firm is a great success, and you decide to expand it by moving to a larger office and buying more computers. As the owner of a small business, you can raise the funds for this expansion in three ways:

1. If you are making a profit, you could reinvest the profits back into your firm. Profits that are reinvested in a firm rather than taken out of the firm and paid to the firm’s owners are called *retained earnings*.
2. You could raise funds by recruiting additional owners to invest in the firm. This arrangement would increase the firm’s *financial capital*.
3. Finally, you could borrow the funds from relatives, friends, or a bank.

The managers of a large public firm have some additional ways to raise funds, as we will see in the next section.

Sources of External Funds

Unless firms rely on retained earnings, they have to raise the *external funds* they need from those who have funds available to invest. It is the role of an economy’s *financial system* to transfer funds from savers to borrowers.

Most firms raise external funds in two ways. The first way, called **indirect finance**, relies on financial intermediaries such as banks. If you put \$1,000 in a checking account or in a certificate of deposit (CD), the bank will loan most of those funds to borrowers. The bank will combine your funds with those of other depositors and, for example, make a \$100,000 loan to a local business. Small businesses rely heavily on bank loans as their primary source of external funds.

A second way for firms to acquire external funds is through *financial markets*. Raising funds in these markets, such as the New York Stock Exchange on Wall Street in New York City, is called **direct finance**. Direct finance usually takes the form of the borrower selling the lender a *financial security*. A financial security is a document—sometimes in electronic form—that states the terms under which the funds are passed from the buyer of the security (who is lending funds) to the borrower. *Bonds* and *stocks* are the two main types of financial securities. Typically, only large corporations are able to sell bonds and stocks on financial markets. Investors are generally unwilling to buy securities issued by small and medium-sized firms because the investors lack sufficient information on the financial health of smaller firms.

Bonds **Bonds** are financial securities that represent promises to repay a fixed amount of funds. When Apple sells a bond to raise funds, it promises to pay the purchaser of the bond an interest payment each year for the term of the bond, as well as a

payment of the loan amount, or the *principal*, at the end of the term. Apple may need to raise many millions of dollars to build new offices, but each individual bond has a principal, or *face value*, of \$1,000, which is the amount each bond purchaser is lending Apple. So, Apple must sell many bonds to raise all the funds it needs. Suppose Apple promises it will pay interest of \$40 per year to anyone who buys one of its bonds. The interest payments on a bond are called **coupon payments**. The **interest rate** is the cost of borrowing funds, usually expressed as a percentage of the amount borrowed. We can calculate the interest rate on the bond, called the *coupon rate*, by dividing the coupon by the face value of the bond. In this case, the coupon rate is:

$$\frac{\$40}{\$1,000} = 0.04, \text{ or } 4\%.$$

Many bonds that corporations issue have terms, or *maturities*, of 30 years. In this example, if you bought a bond from Apple, Apple would pay you \$40 per year for 30 years, and at the end of the thirtieth year, Apple would repay the \$1,000 principal to you.

The interest rate that a corporation selling a bond has to pay depends on how likely bond buyers—investors—think that the corporation is to default, or not make the promised coupon or principal payments. The higher the *default risk* on a bond, the higher the interest rate will be. For example, investors see the federal government as being very unlikely to default on its bonds, so federal government bonds pay a lower interest rate than do bonds of a firm such as Apple. In turn, Apple pays a lower interest rate on its bonds than does a corporation that investors believe is not as likely to make its bond payments.

The Rating Game: Is the U.S. Treasury Likely to Default on Its Bonds?

Federal regulations require that before they can sell bonds to investors, firms and governments must first have bonds rated by one of the credit-rating agencies. The three largest rating agencies are Moody's Investors Service, Standard & Poor's Corporation, and Fitch Ratings.

These private firms rate bonds by giving them letter grades—AAA or Aaa being the highest—that reflect the likelihood that the firm or government will be able to make the payments on the bond. The following table shows the ratings:

	Moody's Investors Service	Standard & Poor's (S&P)	Fitch Ratings	Meaning of the Ratings
Investment-grade bonds	Aaa	AAA	AAA	Highest credit quality
	Aa	AA	AA	Very high credit quality
	A	A	A	High credit quality
	Baa	BBB	BBB	Good credit quality
Non-investment-grade bonds	Ba	BB	BB	Speculative
	B	B	B	Highly speculative
	Caa	CCC	CCC	Substantial default risk
	Ca	CC	CC	Very high levels of default risk
	C	C	C	Exceptionally high levels of default risk
	—	D	D	Default

Note: The entries in the "Meaning of the Ratings" column are slightly modified from those that Fitch uses. The other two rating agencies have similar descriptions. For each rating from Aa to Caa, Moody's adds a numerical modifier of 1, 2, or 3. The rating Aa1 is higher than the rating Aa2, and the rating Aa2 is higher than the rating Aa3. Similarly, Standard & Poor's and Fitch Ratings add a plus (+) or minus (-) sign. The rating AA+ is higher than the rating AA, and the rating AA is higher than the rating AA-.

Investors can use the ratings in deciding how much risk they are willing to accept when buying a bond. Generally, the lower the rating, the higher the interest rate an investor will receive but also the higher the risk that the issuer of the bond will default.

The rating agencies charge firms and governments—rather than investors—for their services. This arrangement raises the question of whether rating agencies face a conflict of interest. Because firms issuing bonds can choose which of the agencies to hire to rate their bonds, the agencies may have an incentive to give higher ratings than might be justified in order to keep the firms' business. During the housing boom of the mid-2000s, some financial firms issued *mortgage-backed bonds*. These bonds were similar to regular corporate bonds except that the interest payments came from mortgage loans people had taken out to buy houses. The money from those mortgage payments was passed along to investors who had bought the mortgage-backed bonds. The rating agencies gave many of these bonds AAA ratings, even though when housing prices began to decline in 2006, many homeowners stopped making their mortgage payments and the value of the bonds declined sharply. Some economists and policymakers believe the rating agencies provided the high ratings primarily to ensure that the firms that issued the bonds would continue to hire them.

Some investors worry that the U.S. government might someday default on the bonds that it has sold. Over the past 15 years, the federal government has been spending more than it has been collecting in taxes. The result is a federal budget deficit, which forces the Treasury to sell bonds equal to the amount of the deficit. The budget deficit was particularly large during and immediately after the 2007–2009 recession, which resulted in sharp declines in tax receipts and increases in government spending. Forecasts from the U.S. Congressional Budget Office indicate that large budget deficits will continue indefinitely because spending on Social Security, Medicare, Medicaid, and other government programs is expected to increase faster than tax revenues.

In 2011, Standard & Poor's (S&P) decided that because of these continuing deficits, it would downgrade U.S. Treasury bonds from AAA to AA+. Never before had a rating agency given Treasury bonds less than an AAA rating.

Is it likely that the U.S. Treasury will default on its bonds? S&P argued that while a default is still unlikely, the continuing large deficits increased the chance that someday the Treasury might not make the interest payments on its bonds. Most investors, though, appear confident that the Treasury will not default and are willing to buy Treasury bonds despite the historically low interest rates on the bonds. Like the Ghost of Christmas Yet to Come in Charles Dickens's *A Christmas Carol*, S&P was giving a warning of something that might happen rather than something that necessarily must happen.

Stock A financial security that represents partial ownership of a firm.

Stocks When you buy a newly issued bond from a firm, you are lending funds to that firm. When you buy **stock** issued by a firm, you are actually buying part ownership of the firm. When a corporation sells stock, it is doing the same thing the owner of a small business does when he or she takes on a partner: The firm is increasing its financial capital by bringing additional owners into the firm. Any one shareholder usually owns only a small fraction of the total shares of stock issued by a corporation.

Many small investors buy shares of *mutual funds* rather than directly buying stocks issued by individual companies. Mutual funds, such as Fidelity Investment's Magellan Fund, sell shares to investors and use the funds to invest in a portfolio of financial assets, such as stocks and bonds. By buying shares in a mutual fund, small investors reduce the costs they would pay to buy many individual stocks and bonds. Small savers who have only enough money to buy a few individual stocks and bonds can use mutual funds to *diversify*, which lowers their investment risk because most mutual funds hold a large number of stocks and bonds. If a firm issuing a stock or bond declares bankruptcy, causing the stock or bond to lose all of its value, the effect on a

mutual fund's portfolio is likely to be small. The effect might be devastating, though, to a small investor who invested most of his or her savings in the stock or bond. Because mutual funds are willing to buy back their shares at any time, they also provide savers with easy access to their money.

Exchange-traded funds (ETFs) are similar to mutual funds in that when you buy shares in an ETF, you are buying a claim to a portfolio of stocks or bonds. But mutual funds can only be bought from or sold back to the firm that issues them. ETFs can be bought and sold to other investors in financial markets, just as individual stocks or bonds can.

A shareholder is entitled to a portion of the corporation's profits, if there are any. Corporations generally keep some of their profits as retained earnings to finance future expansion. The remaining profits are paid to shareholders as **dividends**. If a firm uses its retained earnings to grow and earn economic profits, its share price rises, which provides a *capital gain* for investors. If a corporation is unable to make a profit, it usually does not pay a dividend. Under the law, corporations must make payments on any debt they have before making payments to their owners. That is, a corporation must make promised payments to bondholders before it can make any dividend payments to shareholders. Unlike bonds, stocks do not have a maturity date, so the firm is not obliged to return the investor's funds at any particular date. MyEconLab Concept Check

Stock and Bond Markets Provide Capital—and Information

The original purchasers of stocks and bonds may resell them to other investors. In fact, most of the buying and selling of stocks and bonds that takes place each day involves investors reselling existing stocks and bonds to each other rather than corporations selling new stocks and bonds to investors. The buyers and sellers of stocks and bonds together make up the *stock and bond markets*. There is no single place where stocks and bonds are bought and sold. Some trading of stocks and bonds takes place in buildings known as *exchanges*, such as the New York Stock Exchange or the Tokyo Stock Exchange. In the United States, the stocks and bonds of the largest corporations are traded on the New York Stock Exchange. The development of computer technology has spread the trading of stocks and bonds outside exchanges to *securities dealers* linked by computers. These dealers comprise the *over-the-counter market*. The stocks of many high-technology firms—including Apple, Twitter, and Facebook—are traded in the most important of the over-the-counter markets, the *National Association of Securities Dealers Automated Quotations* system, which is referred to by its acronym, NASDAQ.

Shares of stock represent claims on the profits of the firms that issue them. Therefore, as the fortunes of the firms change and they earn more or less profit, the prices of the stock the firms have issued should also change. Similarly, bonds represent claims to receive coupon payments and one final payment of the principal. Therefore, a particular bond that was issued in the past may have its price go up or down, depending on whether the coupon payments being offered on newly issued bonds are higher or lower than those on existing bonds. If you hold a bond with a coupon of \$30 per year, and similar newly issued bonds have coupons of \$40 per year, the price of your bond will fall because it is less attractive to investors. The price of a bond will also be affected by changes in *default risk*, which reflects investors' expectations of the issuing firm's ability to make the coupon payments. For example, if investors begin to believe that a firm may soon go out of business and stop making coupon payments to its bondholders, the price of the firm's bonds will fall to very low levels.

Changes in the value of a firm's stocks and bonds provide important information for a firm's managers, as well as for investors. An increase in the stock price means that investors are more optimistic about the firm's profit prospects, and the firm's managers might want to expand the firm's operations as a result. By contrast, a decrease in the firm's stock price indicates that investors are less optimistic about the firm's profit prospects, so management may want to shrink the firm's operations. Similarly, changes in the value of the firm's bonds imply changes in the cost of external funds to finance the firm's investment in research and development or in new factories. A higher bond price indicates a lower cost of new external funds, while a lower bond price indicates a higher cost of new external funds. MyEconLab Concept Check

Don't Let This Happen to You

When Twitter Shares Are Sold, Twitter Doesn't Get the Money

Twitter is a popular investment, with investors buying and selling shares often as their views about the value of the firm shift. That's great for Twitter, right? Think of Twitter collecting all that money as shares change hands and the stock price goes up. *Wrong.* Twitter raises funds in a primary market, but its shares trade in a secondary market. Those trades don't put money into Twitter's hands, but they do give important information to the firm's managers. Let's see why.

Primary markets are markets in which firms sell newly issued stocks and bonds to initial buyers. Businesses can raise funds in a primary financial market in two ways—by borrowing (selling bonds) or selling shares of stock—which result in different types of claims on the borrowing firm's future income. Although you may hear about the stock market fluctuations every day in news updates, bonds actually account for more of the funds raised by borrowers. The total value of bonds in the United States is typically about twice the value of stocks.

In *secondary markets*, stocks and bonds that have already been issued are sold by one investor to another.

If Twitter sells shares to the public, it is turning to a primary market for new funds. Once Twitter shares are issued, investors trade the shares in the secondary market. Twitter does not receive any new funds when its shares are traded. The initial seller of a stock or bond raises funds from an investor only in the primary market. Secondary markets convey information to firms' managers and investors by determining the price of stocks and bonds. For example, a major increase in Twitter's stock price conveys the market's optimism about the firm, and Twitter may decide to raise funds to expand. So, secondary markets are valuable sources of information for corporations that are considering raising funds.

Primary and secondary markets are both important, but they play different roles. As an investor, you principally trade stocks and bonds in a secondary market. As a corporate manager, you may help decide how to raise new funds to expand the firm where you work.

The Fluctuating Stock Market

The performance of the U.S. stock market is often measured using *stock market indexes*. Stock market indexes are averages of stock prices, with the value of the index set equal to 100 in a particular year, called the *base year*. Because the stock indexes are intended to show movements in prices from one year to the next, rather than the actual dollar values of the underlying stocks, the year chosen for the base year is unimportant. Figure 8.2 shows movements from January 1998 to June 2015 in the three most widely followed stock indexes (the shaded areas represent months in which the U.S. economy was in a business cycle recession when the production and profits of many firms are falling):

- The Dow Jones Industrial Average, which is an index of the stock prices of 30 large U.S. corporations.
- The S&P 500, which is an index prepared by Standard & Poor's Corporation and includes the stock prices of 500 large U.S. firms.
- The NASDAQ Composite Index, which includes the stock prices of more than 4,000 firms whose shares are traded in the NASDAQ stock market. NASDAQ is an over-the-counter market, meaning that buying and selling on NASDAQ is carried out between dealers who are linked together by computer. The listings on NASDAQ are dominated by high-tech firms such as Apple, Facebook, and Twitter.

As we have seen, ownership of a firm's stock represents a claim on the firm's profits. So, the larger the firm's profits are, the higher its stock price will be. When the overall economy is expanding, incomes, employment, and spending will all increase, as will corporate profits. When the economy is in a recession, incomes, employment, and spending will fall, as will corporate profits. Therefore, we would expect that stock prices will rise when the economy is expanding and fall when the economy is in recession. We see this pattern reflected in the three stock market indexes shown in Figure 8.2. All three

MyEconLab Real-time data

Figure 8.2 Movements in Stock Market Indexes, January 1998 to June 2015

The performance of the U.S. stock market is often measured by market indexes, which are averages of stock prices. The three most important indexes are the Dow Jones Industrial Average, the S&P 500, and the NASDAQ. During the period from 1998 to 2015, the three indexes followed

similar patterns, rising when the U.S. economy was expanding and falling when the economy was in recession. Note that in all three panels, the vertical axis does not start at zero.

indexes follow a roughly similar pattern: increases in stock prices during the economic expansion of the late 1990s, declines after the “dot-com crash” of 2000 and the recession of 2001, increases from late 2001 to late 2007, declines as the U.S. economy entered a recession at the end of 2007, and then increases beginning in early 2009.

The stock prices of many early Internet companies soared in the late 1990s, as some analysts made what turned out to be overly optimistic predictions about how rapidly online retailing would grow. In 2000, when investors realized that many dot-coms would never be profitable, their stock prices crashed. Because the NASDAQ is dominated by high-tech stocks, it experienced greater swings during the dot-com boom and bust of the late 1990s and early 2000s than did the other two indexes. The sharp declines in all three indexes beginning in late 2007 reflected the severity of the recession that began in December of that year. The severity of the recession was due in part to problems with financial firms, which we will discuss in Section 8.4. By 2015, as recovery from the recession continued, all three indexes had reached their highest values ever.

Why Are Many People Poor Stock Market Investors?

You’ve probably heard this standard advice about investing: “Buy low and sell high.” That is, you should buy shares of stocks and other financial assets when their prices are low and sell them when their prices are high. Unfortunately, many people do the opposite. For instance, many people bought shares of Apple stock when it was selling for more than \$700 per share in September 2012 and sold when it was below \$400 per share in April 2013.

Stock prices are difficult to predict, but many people convince themselves that a stock whose price has been rising will continue to rise and that a stock whose price has been falling will continue to fall. As a result, people end up buying high and selling low rather than the reverse. Studies have shown that individual investors consistently earn lower returns on their investments when they frequently buy and sell stock hoping to predict changes in stock prices.

New information about Twitter’s future profitability would cause the price of its stock to change.

But why are stock prices so difficult to predict? The key reason is that stock prices are based less on the *current* profitability of firms than on their *expected* future profitability. After all, few investors would be willing to pay a high price for a stock that was profitable today but was expected to suffer large losses tomorrow. Similarly, investors in late 2015 were willing to pay \$30 per share for Twitter even though the firm was suffering losses because they expected it would earn profits in the future. If you look carefully at Figure 8.2, you can see that stock prices start to rise when investors begin to expect an economic recovery will soon begin rather than after the recovery has already begun.

Many Wall Street investment professionals spend a lot of time and money gathering all possible information about the future profitability of firms, hoping to buy stock in the most profitable firms. As a result, all of the information publicly available about a firm is reflected in the firm's stock price. For example, if at the end of a particular day, Twitter is selling for \$30 per share, that price reflects all of the information available about Twitter's future profitability. What might cause Twitter's stock price to change? *Only new information about its future profitability.* For example, if Twitter releases new data showing that its advertising sales have been lower than investors had expected, its stock price will fall.

Even highly paid professional investors cannot consistently predict stock prices. The managers of mutual funds who try to earn high returns by frequently buying and selling stocks are rarely able to beat the stock market averages, such as the S&P 500. One study found that, in a typical year, only one-third of mutual fund managers were able to earn their investors a higher return than a small investor could earn by investing in an index mutual that buys only the stocks in the S&P 500. Only 10 percent of mutual fund managers earned a higher return than an index fund for two consecutive years.

Whichever way you—or Wall Street professionals—predict stock prices will move in the future, you are as likely to be wrong as you are to be right.

Why Does Warren Buffett Like Mutual Funds?

Warren Buffett is considered one of the greatest investors who has ever lived. His ability to predict which firms' stocks are likely to rise in price helped make him one of the richest people in the world. Yet Buffett advises that individual investors not try to pick individual stocks but

instead use 90 percent of their savings to buy shares in mutual funds that charge low fees, such as those offered by the Vanguard Group. Is it likely that anyone investing mostly in mutual funds will become as wealthy as Buffett? Why would Buffett give this advice?

Solving the Problem

Step 1: Review the chapter material. This problem is about investing in the stock market, so you may want to review the section “The Fluctuating Stock Market” on page 318 and the *Making the Connection*, “Why Are Many People Poor Stock Market Investors?” which begins on page 319.

Step 2: Answer the first question by discussing whether investing in low-cost mutual funds is a way to become as wealthy as Warren Buffett. Most investors who have become wealthy have done so by making large investments in just a few firms. Mutual funds typically hold large numbers of stocks

and bonds, so even if one or two of the stocks do extremely well, the total investment return from the fund will be held back by the smaller increases (or losses) in the other stocks in the fund. By investing in mutual funds, you can accumulate significant amounts to pay for a house, a college education, or retirement. Many people who have earned only middle-class incomes have accumulated a million dollars or more by retirement age by investing in low-cost mutual funds. But no one is known to have become fabulously wealthy with this approach to saving.

Step 3: Answer the second question by explaining why Warren Buffett would advise most people to put their savings in mutual funds, even though they are unlikely to become wealthy by doing so. Mutual funds give individual investors a low-cost way to diversify. Although it's possible to earn a high return investing in the stocks of individual firms, it's also easy for a small investor to lose all of his or her money if those firms run into financial problems.

Extra Credit: Warren Buffett may have become a billionaire by being better than other investors at predicting the future profits of the firms he invests in. Or he may have become a billionaire because he was lucky that the firms he invested in did particularly well—in which case he may not be better at forecasting the future profitability of firms than are other investors. Given that nearly all other equally intelligent and hardworking professional investors have been unable to consistently “beat the market” by earning higher returns than those earned by the typical low-cost, well-diversified mutual fund, it is impossible to know with certainty the true reasons for Buffett's success.

Using Financial Statements to Evaluate a Corporation

LEARNING OBJECTIVE: Understand the information corporations include in their financial statements.

To raise funds, a firm's managers must persuade potential lenders or investors that the firm will be profitable. Before a firm can sell new issues of stocks or bonds, it must first provide investors and financial regulators with information about its finances. To borrow from a bank, a firm must also provide the bank with financial information.

In most high-income countries, government agencies require firms to disclose specific financial information to the public before they are allowed to sell securities such as stocks or bonds in financial markets. In the United States, the Securities and Exchange Commission (SEC) requires publicly owned firms to report their performance in financial statements prepared using standard accounting methods, often referred to as *generally accepted accounting principles*. Such disclosure reduces the cost to investors of gathering information about firms, but it doesn't eliminate these costs—for two reasons. First, some firms may be too young to have much information for potential investors to evaluate. Second, managers may try to present the required information in the most favorable way so that investors will overvalue their securities.

Private firms also collect information on business borrowers and sell the information to lenders and investors. If the information-gathering firms do a good job, lenders and investors purchasing the information will be better able to judge the quality of borrowing firms. Some firms—including Moody's Investors Service, Standard & Poor's Corporation, Value Line, and Dun & Bradstreet—collect information from businesses and sell it to subscribers. Buyers include individual investors, libraries, and financial intermediaries. You can find some of these publications in your college library or through online information services.

Liability Anything owed by a person or a firm.

Income statement A financial statement that shows a firm's revenues, costs, and profit over a period of time.

Accounting profit A firm's net income, measured as revenue minus operating expenses and taxes paid.

Opportunity cost The highest-valued alternative that must be given up to engage in an activity.

Explicit cost A cost that involves spending money.

Implicit cost A nonmonetary opportunity cost.

What kind of information do investors and firm managers need? A firm must answer three basic questions: What to produce? How to produce it? What price to charge? To answer these questions, a firm's managers need two pieces of information: The first is the firm's revenues and costs, and the second is the value of the property and other assets the firm owns and the firm's debts, or other **liabilities**, that it owes to households and other firms. Potential investors in the firm also need this information to decide whether to buy the firm's stocks or bonds. The information can be found in the firm's *financial statements*, principally its income statement and balance sheet, which we discuss next.

MyEconLab Concept Check

The Income Statement

A firm's **income statement** shows its revenues, costs, and profit over a period of time. Corporations issue annual income statements, although the 12-month *fiscal year* covered may be different from the calendar year to better represent the seasonal pattern of the business. We explore income statements in greater detail in the appendix to this chapter.

Accounting Profit An income statement shows a firm's revenue, costs, and profit for the firm's fiscal year. To determine profitability, the income statement starts with the firm's revenue and subtracts its operating expenses and taxes paid. The remainder, *net income*, is the **accounting profit** of the firm.

Economic Profit Accounting profit provides information on a firm's current net income, measured according to accepted accounting standards. Accounting profit is not, however, the ideal measure of a firm's profits because it neglects some of the firm's costs. *Economic profit* provides a better indication than accounting profit of how successful a firm is because economic profit is calculated using all of a firm's costs. Firms making an economic profit will remain in business and may even expand. Firms making an *economic loss* are unlikely to remain in business in the long run. To understand how economic profit is calculated, remember that economists always measure cost as *opportunity cost*. The **opportunity cost** of any activity is the highest-valued alternative that must be given up to engage in that activity. Costs are either *explicit* or *implicit*. When a firm spends money, an **explicit cost** results. If a firm incurs an opportunity cost but does not spend money, an **implicit cost** results. For example, firms incur an explicit labor cost when they pay wages to employees. Firms have many other explicit costs as well, such as the cost of the electricity used to light their buildings or the costs of advertising or insurance.

Some costs are implicit, however. The most important of these is the opportunity cost to investors of the funds they have invested in the firm. Economists use the term *normal rate of return* to refer to the minimum amount that investors must earn on the funds they invest in a firm, expressed as a percentage of the amount invested. If a firm fails to provide investors with at least a normal rate of return, it will not be able to remain in business over the long run because investors will not continue to invest their funds in the firm. For example, Borders was once the second-largest bookstore chain in the United States and a very profitable firm, with stock that sold for more than \$40 per share. By 2010, investors became convinced that the firm's difficulty competing with Amazon and other online booksellers and its loss of sales to e-books meant that the firm would never be able to provide investors with a normal rate of return. Many investors expected that the firm would eventually have to declare bankruptcy, and as a result, the price of Borders stock plummeted to less than \$1 per share. Within a year, the firm declared bankruptcy, and its remaining assets were sold off. The return (in dollars) that investors require to continue investing in a firm is a true cost to the firm and should be subtracted from the firm's revenues to calculate its profits.

The rate of return that investors require to continue investing in a firm varies from firm to firm. If the investment is risky—as would be the case with a biotechnology startup—investors may require a high rate of return to compensate them

for the risk. Investors in firms in more established industries, such as electric utilities, may require lower rates of return. The exact rate of return investors require to invest in any particular firm is difficult to calculate, which also makes it difficult for an accountant to include the return as a cost on an income statement. Firms have other implicit costs, besides the return investors require, that can also be difficult to calculate. As a result, the rules of accounting generally require that only explicit costs be included in the firm's financial records. *Economic costs* include both explicit costs and implicit costs. **Economic profit** is equal to a firm's revenues minus its economic costs. Because accounting profit excludes some implicit costs, it is larger than economic profit.

MyEconLab Concept Check

Economic profit A firm's revenues minus all of its implicit and explicit costs.

The Balance Sheet

A firm's **balance sheet** shows its financial position on a particular day, usually the end of a quarter or year. Recall that an asset is anything of value that a firm owns, and a liability is a debt or an obligation owed by a firm. Subtracting the value of a firm's liabilities from the value of its assets leaves its *net worth*. We can think of the net worth as what the firm's owners would be left with if the firm were closed, its assets were sold, and its liabilities were paid off. Investors can determine a firm's net worth by inspecting its balance sheet. We analyze a balance sheet in more detail in the appendix to this chapter.

Corporate Governance Policy and the Financial Crisis of 2007–2009

LEARNING OBJECTIVE: Explain the role that corporate governance problems may have played in the financial crisis of 2007–2009.

Accurate and easy-to-understand financial statements help the firm's managers make decisions and provide information to investors who are considering buying the firm's stock or bonds. In fact, the information in financial statements helps guide resource allocation in the economy.

Firms disclose financial statements in periodic filings to the federal government and in *annual reports* to shareholders. An investor is more likely to buy a firm's stock if the firm's income statement shows a large after-tax profit and if its balance sheet shows a large net worth. The top management of a firm has at least two reasons to attract investors and keep the firm's stock price high. First, a higher stock price increases the funds the firm can raise when it sells a given amount of stock. Second, to reduce the principal–agent problem, boards of directors often tie the salaries of top managers to the firm's stock price or to the profitability of the firm.

Top managers clearly have an incentive to maximize the profits reported on the income statement and the net worth reported on the balance sheet. If top managers make good decisions, the firm's profits will be high, and the firm's assets will be large relative to its liabilities. Problems that surfaced during the early 2000s, however, revealed that some top managers have inflated profits and hidden liabilities that should have been listed on their balance sheets. At other firms, managers took on more risk than they disclosed to investors. We will explore problems with corporate governance and the government's reaction to these problems by discussing the accounting scandals of the early 2000s and problems that many financial firms encountered during 2007–2009.

The Accounting Scandals of the Early 2000s

In the early 2000s, the top managers of several well-known firms, including Enron, an energy trading firm, and WorldCom, a telecommunications firm, falsified their firms' financial statements in order to mislead investors about how profitable the firms actually were. Several top managers were sentenced to long prison terms, and some of the firms, including Enron, went out of business.

How was it possible for corporations such as Enron and WorldCom to falsify their financial statements? The federal government regulates how financial statements are prepared, but this regulation cannot by itself guarantee the accuracy of the statements. All firms that issue stock to the public have certified public accountants working for outside firms *audit* their financial statements. Unfortunately, as the Enron and WorldCom scandals revealed, top managers who are determined to deceive investors about the true financial condition of their firms can also deceive outside auditors.

To guard against future scandals, new federal legislation was enacted in 2002. The landmark *Sarbanes-Oxley Act* of 2002 requires that CEOs personally certify the accuracy of financial statements. The Sarbanes-Oxley Act also requires that financial analysts and auditors disclose whether any conflicts of interest might exist that would limit their independence in evaluating a firm's financial condition. On balance, most observers acknowledge that the Sarbanes-Oxley Act increased confidence in the U.S. corporate governance system. However, as we will discuss in the next section, problems during 2007–2009 at financial firms again raised questions about whether corporations were adequately disclosing information to investors.

MyEconLab [Concept Check](#)

The Financial Crisis of 2007–2009

Beginning in 2007 and lasting into 2009, the U.S. economy suffered the worst financial crisis since the Great Depression of the 1930s. At the heart of the crisis was a problem in the market for home mortgages. When people buy houses, they typically borrow the money by taking out a mortgage loan from a bank or another financial institution. The house they are buying is pledged as collateral for the loan, meaning that the bank can take possession of the house and sell it if the borrower defaults by failing to make the payments on the loan.

Securitizing Home Mortgages For many years, a bank or other financial institution granting a mortgage would keep the loan until the borrower had paid it off. Beginning in the 1970s, financial institutions began *securitizing* some mortgage loans, which means that groups of mortgages were bundled together and sold to investors. These *mortgage-backed securities* are very similar to bonds in that the investor who buys one receives regular interest payments, which in this case come from the payments being made on the original mortgage loans. At first, the securitization process was carried out by the Federal National Mortgage Association (“Fannie Mae”) and the Federal Home Loan Mortgage Corporation (“Freddie Mac”), which Congress had established to help increase the volume of lending in the home mortgage market. Fannie Mae and Freddie Mac would buy mortgages granted to creditworthy borrowers and bundle them into securities that were then sold to investors.

Looser Lending Standards Fuel a Housing Bubble Beginning in the 1990s, private financial firms, primarily investment banks, started to securitize mortgages. By the early 2000s, banks and other financial institutions were loosening the standards for granting mortgages. Lenders began granting mortgages to “subprime” borrowers, whose credit histories included failing to pay all of their bills on time, and “Alt-A” borrowers, who failed to document that their incomes were high enough to afford their mortgage payments. The ease of obtaining a mortgage increased demand for housing, and caused prices to soar. This housing bubble began to deflate in mid-2006, with prices in many cities beginning a sharp downturn. By 2007, many borrowers—particularly subprime and Alt-A borrowers—began to default on their mortgages. These defaults were bad news for anyone owning mortgage-backed securities because the value of these securities depended on steady payments being made on the underlying mortgages. As prices of these securities plunged, the result was a financial crisis as many financial institutions suffered heavy losses, and some of the largest of them remained in business only because they received aid from the federal government. Some economists argue that the firms did a poor job of correctly assessing the risk of the investments

they made in these securities. This failure may be an indication of poor corporate governance if top managers were unable to effectively monitor the employees who were deciding to invest in risky securities.

Government Regulation in Response to the Financial Crisis During the financial crisis, many investors complained that they weren't aware of the riskiness of some of the assets—particularly mortgage-backed securities—on the balance sheets of financial firms. Some observers believed that the managers of many financial firms had intentionally misled investors about the riskiness of these assets. Others argued that the managers themselves had not understood how risky the assets were. In the fall of 2008, Fannie Mae and Freddie Mac were brought under direct control of the government. As the crisis passed, in July 2010, Congress overhauled the regulation of the financial system with the passage of the **Wall Street Reform and Consumer Protection Act**, referred to as the **Dodd-Frank Act**. Among its provisions, the act created the Consumer Financial Protection Bureau, housed in the Federal Reserve—the central bank of the United States—to write rules intended to protect consumers in their borrowing and investing activities. The act also established the Financial Stability Oversight Council, which includes representatives from all the major federal financial regulatory bodies, including the SEC and the Federal Reserve. The council is intended to identify and act on risks to the financial system. Economists are divided in their opinions about whether the Dodd-Frank Act will significantly reduce the risk of future financial crises.

Did Principal-Agent Problems Help Cause the 2007–2009 Financial Crisis?

As we have seen, the process of securitizing mortgages played an important role in the financial crisis of 2007–2009. Beginning in the 1990s, private investment banks began to securitize mortgages. Unlike commercial banks, whose main activities are accepting deposits and making loans, investment banks had traditionally concentrated on providing advice to corporations on selling new stocks and bonds and on *underwriting* the issuance of stocks and bonds by guaranteeing a price to the firm selling them. Investment banking is considered riskier than commercial banking because investment banks can suffer substantial losses on underwriting. To address this greater risk, Congress passed the *Glass-Steagall Act* in 1933. The act prevented financial firms from being both commercial banks and investment banks.

Some economists and policymakers argued that Glass-Steagall reduced competition for investment banking services by prohibiting commercial banks from offering these services. Congress repealed the Glass-Steagall Act in 1999, after which some commercial banks began engaging in investment banking. Many of the largest, best-known investment banks, such as Lehman Brothers, Bear Stearns, Goldman Sachs, Merrill Lynch, and Morgan Stanley, remained exclusively investment banks. The mortgage-backed securities originated by the investment banks were mostly sold to investors, but some were retained as investments by these firms. As a result, when the prices of these securities declined beginning in 2007, the investment banks suffered heavy losses. Lehman Brothers was forced to declare bankruptcy; Merrill Lynch and Bear Stearns were sold to commercial banks in deals arranged by the U.S. government; and Goldman Sachs and Morgan Stanley became bank holding companies, which allowed them to engage in commercial banking activity.

Why did investment banks take on so much risk by originating securities backed by mortgages granted to borrowers who had a significant likelihood of defaulting on the loans? Michael Lewis, a financial journalist and former Wall Street bond salesman, has argued that a key reason was a change in how the investment banks were organized. Traditionally, large Wall Street investment banks had been organized as partnerships, but by 2000 they had all converted to being publicly traded corporations. As we have seen, in a partnership, the funds of the relatively

small group of owners are put directly at risk, and the principal–agent problem is reduced because there is little separation of ownership from control. With a publicly traded corporation, on the other hand, the principal–agent problem can be severe. Lewis argues:

No investment bank owned by its employees would have ... bought and held \$50 billion in [exotic mortgage-backed securities] ... or even allow [these securities] to be sold to its customers. The hoped-for short-term gain would not have justified the long-term hit.

Issues of corporate governance will clearly continue to be a concern for economists, policymakers, and investors.

Will Dodd-Frank Improve Corporate Governance?

Commercial and investment banks, mutual funds, and brokerage firms are often called *financial service firms*. A review of the effects of the Dodd-Frank Act by an accountant included the opinion that, “Clearly, the drive for improved

governance in financial services will continue for years to come.” What does the author mean by “improved governance”? Why has improved governance at financial service firms been a significant policy issue?

Solving the Problem

Step 1: Review the chapter material. This problem is about whether government regulation can reduce the principal–agent problem in financial firms, so you may want to review the section “Government Regulation in Response to the Financial Crisis” and the section “Did Principal–Agent Problems Help Cause the 2007–2009 Financial Crisis?” which are both on page 325.

Step 2: Answer the first question by explaining what “improved governance” means. Some economists argue that one factor that caused the financial crisis of 2007–2009 was top managers of large financial services firms making riskier investments than were in the best interests of the firms’ shareholders. Some economists also argue that financial service firms should have done a better job of assessing the risk involved in investing in mortgage-backed securities. Better governance in this context refers to improvements in aligning the actions of top managers with the preferences of shareholders and in improving the assessment and monitoring of investments.

Step 3: Answer the second question by explaining why improved governance at financial service firms has become a political issue. Policymakers recognize that poor corporate governance may have played a role in the financial crisis. Given its severity, they have been looking for ways to increase the stability of the financial system.

Extra Credit: Many economists and policymakers are hopeful that the Dodd-Frank Act has improved governance at financial service firms. Some economists, though, believe that the administrative costs the act imposes on firms may be greater than any benefits from improved governance. Some economists have also criticized other provisions of the act that restrict the monetary policy actions the Federal Reserve may take in a financial crisis.

Economics in Your Life

Would You Pay to Use Facebook or Twitter?

At the beginning of the chapter, we asked you to consider two questions: Would you be willing to pay to use social media apps such as Facebook and Twitter if the apps no longer targeted you with ads? and Do you think other users would be willing to pay enough that firms could rely on that source of revenue? The answer to the first question is likely to depend on what price the apps would charge, what your income is, and how annoyed you are by targeted ads. Of course, some people find the information in targeted ads useful and would prefer to see the ads rather than pay any fee.

In practice, people have become increasingly reluctant to pay anything to download and use an app. Some free apps are downloaded millions of times, while very similar apps that charge a small fee have significantly fewer downloads. In a given year, only about one-third of smartphone or tablet owners will pay for any apps. App developers have mostly adopted the business model of allowing their apps to be downloaded and used for free, while trying to still earn money from users. For instance, the popular games *Clash of Clans* and *Candy Crush Saga* can be downloaded and played for free. The developers earn a profit from people who pay to play the game faster, get extra turns, or otherwise receive benefits not available to those who play for free. The usefulness of social media apps increases as more people use them. If only a few people were on Facebook or used Twitter, these apps wouldn't be much fun. So, these apps can't afford the significant decline in users that would likely occur if they began to charge a fee. The remaining users who were paying would likely find the apps less fun because fewer people would be on them, and they might gradually stop using them.

So, whether you like targeted ads or hate them, it seems likely that you will have to continue putting up with them on social media apps.

Conclusion

In a market system, firms make independent decisions about which goods and services to produce, how to produce them, and what prices to charge. In modern high-income countries, such as the United States, large corporations account for a majority of the sales and profits earned by firms. Generally, the managers of these corporations do a good job of representing the interests of stockholders while providing the goods and services demanded by consumers. As the business scandals of the early 2000s and the problems with financial firms in 2007–2009 showed, however, the principal–agent problem can sometimes become severe. Economists debate the costs and benefits of regulations proposed to address these problems.

8.1 Types of Firms, pages 310–314

LEARNING OBJECTIVE: Categorize the major types of firms in the United States.

Summary

There are three types of firms: A **sole proprietorship** is a firm owned by a single individual and not organized as a corporation; a **partnership** is a firm owned jointly by two or more persons and not organized as a corporation; and a **corporation** is a legal form of business that provides its owners with limited liability. An **asset** is anything of value owned by a person or a firm. The owners of sole proprietorships and partnerships have unlimited liability, which means there is no legal distinction between the personal assets of the owners of the business and the assets of the business. The owners of corporations have **limited liability**, which means they can never lose more than their investment in the firm. Although only 18 percent of firms are corporations, they account for the majority of revenue and profits earned by all firms. **Corporate governance** refers to the way in which a corporation is structured and the effect a corporation's structure has on the firm's behavior. Most corporations have a similar management structure: The shareholders elect a board of directors that appoints the corporation's top managers, such as the chief executive officer (CEO). Because top managers often do not own a large fraction of the stock in the corporation, large corporations have a **separation of ownership from control**. When top managers have less incentive to increase the corporation's profits than to increase their own salaries and their own enjoyment, corporations can suffer from the **principal–agent problem**. The principal–agent problem exists when the principals—in this case, the shareholders of the corporation—have difficulty getting the agent—the corporation's top management—to carry out their wishes.

Review Questions

- 1.1 What are the three major types of firms in the United States? Briefly discuss the most important characteristics of each type.
- 1.2 What is limited liability? Why does the government grant limited liability to the owners of corporations?
- 1.3 Why is limited liability more important for firms trying to raise funds from a large number of investors than

for firms trying to raise funds from a small number of investors?

- 1.4 Explain the circumstances under which it is advantageous to set up a business as a sole proprietorship. Are those circumstances different from those favoring a corporation set-up? Briefly explain.
- 1.5 Unlike in the United States, in Italy many firms employ fewer than 10 people. Would this imply that tax exemptions for small businesses are more effective in stimulating the Italian economy than in the United States?

Problems and Applications

- 1.6 Suppose that shortly after graduating from college, you decide to start your own business. Will you be likely to organize the business as a sole proprietorship, a partnership, or a corporation? Explain your reasoning.
- 1.7 An article discussing the reasons that the Connecticut state legislature passed a general incorporation law observes that prior to the passage of the law, investors were afraid that large businesses “were not a safe bet for their money.” Briefly explain the author's reasoning.

- 1.8 (Related to the **Making the Connection on page 312**) Small firms represent a more vital resource for the future growth prospects of an economy than large firms do. What would you infer from such a statement?
- 1.9 According to an article in the *Economist*, historian David Faure has argued that the Chinese economy failed to grow rapidly during the nineteenth century because “family-run companies ... could not raise sufficient capital to exploit the large-scale opportunities tied to the rise of the steam engine, notably railways and (with limited exceptions) global shipping and automated manufacturing.” How did the United States solve the problem of firms raising enough funds to operate railroads and other large-scale businesses?
Source: “The PCCW Buy-Out in Court,” *Economist*, April 21, 2009.

1.10 (Related to the Making the Connection on page 312) Two economists at the Brookings Institution argue that “new firms rather than existing ones have accounted for a disproportionate share of disruptive and thus highly productivity enhancing innovations in the past—the automobile, the airplane, the computer and personal computer, air conditioning, and Internet search, to name just a few.”

- Why might new firms be more likely than older firms to introduce “disruptive” innovations?
- Assuming these economists are correct about the most important source of productivity enhancing innovations, what are the implications for the future of the U.S. economy of recent trends in the formation of new businesses?

1.11 (Related to the Making the Connection on page 312) An Associated Press article noted that some groups have filed law suits over what the groups describe as “overzealous licensing schemes, in occupations such as hair braiders, yoga teachers and casket makers.”

- What effect might such government licensing requirements have on the rate of new businesses being formed?
- Given your answer to part (a), why might state and local governments pass such licensing requirements?

1.12 In light of the principal–agent problem, comment on the lack of management layers as one of the advantages of sole proprietorships. Why could it be a problem for a firm to have two separate individuals as the principal (the owner) and the agent (the manager)?

1.13 Principal–agent problems usually affect large corporations, more than small businesses. Explain why asymmetric information plays a role, devise a strategy to eliminate it, and discuss the potential problems in implementing such a strategy.

1.14 Salespeople, whether selling life insurance, automobiles, or pharmaceuticals, typically get paid on commission instead of a straight hourly wage. How does paying a commission help solve the principal–agent problem between the owners of a business and their salespeople?

1.15 Private equity firms, such as Blackstone and Kohlberg Kravis Roberts & Co., search for firms where the managers appear not to be maximizing profits. A private equity firm can buy stock in these firms and have its employees elected to the firms’ boards of directors and may even acquire control of the targeted firm and replace the top management. Does the existence of private equity firms reduce any problems in corporate governance? Briefly explain.

How Firms Raise Funds, pages 314–321

LEARNING OBJECTIVE: Explain how firms raise the funds they need to operate and expand.

Summary

Firms rely on retained earnings—which are profits kept by the firm and not paid out to the firm’s owners—or on using the savings of households for the funds they need to operate and expand. With **direct finance**, the savings of households flow directly to businesses when investors buy **stocks** and **bonds** in financial markets. With **indirect finance**, savings flow indirectly to businesses when households deposit money in savings and checking accounts in banks and the banks lend these funds to businesses. Federal, state, and local governments also sell bonds in financial markets, and households also borrow funds from banks. When a firm sells a bond, it is borrowing money from the buyer of the bond. Firms make **coupon payments** to buyers of bonds. The **interest rate** is the cost of borrowing funds, usually expressed as a percentage of the amount borrowed. When a firm sells stock, it is selling part ownership of the firm to the buyer of the stock. **Dividends** are payments by a corporation to its shareholders. The original purchasers of stocks and bonds may resell them in stock and bond markets, such as the New York Stock Exchange. The performance of the U.S. stock market is often measured using stock market indexes. The three most widely followed stock indexes are the Dow Jones Industrial Average, the S&P 500, and the NASDAQ Composite Index.

Review Questions

- What is the difference between direct finance and indirect finance? If you borrow money from a bank to buy a new car, are you using direct finance or indirect finance?
- Why is a bond considered to be a loan but a share of stock is not? Why do corporations issue both bonds and shares of stock?
- How do the stock and bond markets provide information to businesses? Why do stock and bond prices change over time?

Problems and Applications

- Suppose that a firm in which you have invested is losing money. Would you rather own the firm’s stock or the firm’s bonds? Briefly explain.
- Suppose you originally invested in a firm when it was small and unprofitable. Now the firm has grown to be large and profitable. Would you be better off if you had bought the firm’s stock or the firm’s bonds? Briefly explain.
- If you deposit \$20,000 in a savings account at a bank, you might earn 1 percent interest per year. Someone who borrows \$20,000 from a bank to buy a new car might have to pay an interest rate of 6 percent per year on the loan. Knowing this, why don’t you just lend your money directly to the car buyer and cut out the bank?

- 2.7 (Related to the Chapter Opener on page 309) Were the shares of stock issued as a result of Twitter's initial public offering (IPO) sold in a primary market or a secondary market? Was the IPO an example of direct finance or indirect finance?
- 2.8 (Related to the Making the Connection on page 315) According to an article in the *Wall Street Journal*, in May 2015, Moody's Investors Service cut its rating on McDonald's bonds from A3 to A2.
- What is Moody's top bond rating? Under what circumstances would Moody's, or the other bond rating agencies, be likely to cut the rating on a firm's bonds?
 - What will be the likely result of this rating's cut for the interest rate McDonald's will have to pay when it sells new bonds? Briefly explain.
- Source:** Chelsey Dulaney, "Moody's Downgrades McDonald's, Following S&P and Fitch," *Wall Street Journal*, May 15, 2015.
- 2.9 (Related to the Making the Connection on page 315) Investors use the bond ratings from Moody's, S&P, and Fitch to determine which bonds they will buy and the prices they are willing to pay for them. The rating services charge the firms and governments that issue bonds, rather than investors, for their services. Critics argue that the rating agencies may give higher ratings than are justified in order to continue to sell their services to bond issuing firms. To avoid this impression, why don't Moody's, S&P, and Fitch sell their services directly to investors?
- 2.10 What effect would the following events be likely to have on the price of Google's stock?
- A competitor launches a search engine that is better than Google's.
 - The corporate income tax is abolished.
 - Google's board of directors becomes dominated by close friends and relatives of its top management.
 - The price of wireless Internet connections in developing countries unexpectedly drops, so more and more people worldwide use the Internet.
 - Google announces a profit of \$10 billion, but investors anticipated that Google would earn a profit of \$11 billion.
- 2.11 (Related to the Don't Let This Happen to You on page 318) Briefly explain whether you agree with the following statement: "The total value of the shares of Microsoft stock traded on the NASDAQ last week was \$250 million, so the firm actually received more revenue from stock sales than from selling software."
- 2.12 (Related to the Making the Connection on page 319) A column in the *Wall Street Journal* listed "trying to forecast what stocks will do next" as one of the three mistakes investors make repeatedly. 8.3

Using Financial Statements to Evaluate a Corporation, pages 321–323

LEARNING OBJECTIVE: Understand the information corporations include in their financial statements.

Summary

A firm's **income statement** shows its revenues, costs, and profit over a period of time. A firm's **balance sheet** shows its financial position on a particular day, usually the end of a quarter or year. A balance sheet records a firm's assets and liabilities. A **liability** is anything owed by a person or a firm. Firms report their **accounting profit** on their income statements. Accounting profit does not always include all of a firm's **opportunity cost**. **Explicit cost** is a cost that involves spending money. **Implicit cost** is a non-monetary opportunity cost. Because accounting profit excludes some implicit costs, it is larger than **economic profit**.

MyEconLab Visit www.myeconlab.com to complete select exercises online and get instant feedback.

Review Questions

- What does a firm's balance sheet contain? How can the net worth of a firm be calculated using its balance sheet?
- Define income statement and briefly list and explain what it contains.

- Distinguish between a firm's explicit costs and its implicit costs and between a firm's accounting profit and its economic profit.
- Would a business be expected to survive in the long run if it earned a positive accounting profit but a negative economic profit? Briefly explain.

Problems and Applications

- Paolo currently has \$100,000 invested in bonds that earn him 10 percent interest per year. He wants to open a pizza restaurant and is considering either selling the bonds and using the \$100,000 to start his restaurant or borrowing \$100,000 from a bank, which would charge him an annual interest rate of 7 percent. He finally decides to sell the bonds and not take out the bank loan. He reasons, "Because I already have the \$100,000 invested in the bonds, I don't have to pay anything to use the money. If I take out the bank loan, I have to pay interest, so my costs of producing pizza will be higher if I take out the loan than if I sell the bonds." Evaluate Paolo's reasoning.

- 3.6 Think about the balance sheet of a firm. Why is it also known as the “statement of financial position?” Why does the value on the left side of the balance sheet always equal the value of the right-hand side?
- 3.7 Dane decides to give up a job earning \$200,000 per year as a corporate lawyer and converts the duplex that he owns into a UFO museum. (He had been renting out the duplex for \$20,000 a year.) His explicit costs are \$75,000 per year paid to his assistants and \$10,000 per year for utilities. Fans flock to the museum to see his collection of extraterrestrial paraphernalia, which he could easily sell on eBay for \$1,000,000. Over the course of the year, the museum brings in revenues of \$200,000.
- a. How much is Dane’s accounting profit for the year?
b. Is Dane earning an economic profit? Explain.
- 3.8 Twitter was founded in 2006, but it wasn’t until 2013 that Twitter filed its first annual report with the Securities and Exchange Commission (SEC). Briefly explain why.
- 3.9 Jay Ritter, a professor at the University of Florida, was quoted in the *Wall Street Journal* as saying about Facebook: “It’s entirely possible for a company to have solid growth prospects while its stock is overvalued.”
- a. What does it mean to say that a stock is “overvalued?”
b. Why might a firm’s stock be overvalued despite the firm having “solid growth prospects?”

Corporate Governance Policy and the Financial Crisis of 2007–2009, pages 323–326

LEARNING OBJECTIVE: Explain the role that corporate governance problems may have played in the financial crisis of 2007–2009.

Summary

Because their compensation often rises with the profitability of the corporation that employs them, top managers have an incentive to overstate the profits reported on their firm’s income statements. During the early 2000s, it became clear that the top managers of several large corporations had done this, even though intentionally falsifying financial statements is illegal. The *Sarbanes-Oxley Act* of 2002 took several steps intended to increase the accuracy of financial statements and increase the penalties for falsifying them. The financial crisis of 2007–2009 revealed that many financial firms held assets that were far riskier than investors had realized. Congress passed the **Wall Street Reform and Consumer Protection Act (Dodd-Frank Act)** in July 2010 to address some of the issues raised by the financial crisis of 2007–2009.

- 4.6 (Related to **Solved Problem 8.4 on page 326**) An article on *forbes.com* about corporate fraud stated that “misleading accounting and disclosure practices weaken the integrity of capital markets.” The article noted that using incentive contracts for top managers can create a “perverse” incentive to manipulate stock prices because their (executive) total package is based on stock price appreciation.”

- a. Why do financial markets depend on accurate accounting and disclosure practices? Why can misleading accounting and disclosure practices weaken the integrity of financial markets?
b. Why do corporate boards of directors sometimes link top managers’ compensation to the corporations’ stock prices? Briefly explain how tying compensation too closely to stock prices might create an incentive for corporate fraud.

Real-Time Data Exercises

- D8.1 (Exploring stock data)** On June 19, 2015 the closing price of a share of Facebook stock was \$82.51. About 21.5 million shares of stock were traded on this date. Go to wsj.com for a recent trading day and use Facebook's stock symbol (FB) to find the following.
- The closing price of Facebook stock
 - The market value of the shares traded
 - The number of shares (volume) traded
 - The total number of shares outstanding
 - The number of shares traded relative to the number of shares outstanding
- D8.2 (The stock market and recessions)** Go to the Web site of the Federal Reserve Bank of St. Louis (FRED) (research.stlouisfed.org/fred2/) and download and graph the data series for the Nasdaq Composite Index from February 1971 until the most recent day available. Go to the Web site of the National Bureau of Economic Research (nber.org) and find the dates for business cycle peaks and troughs (the period between a business cycle peak and trough is a recession). Describe how stock prices move just before, during, and just after a recession. Is the pattern the same across recessions?
- D8.3 (Exploring dividends)** Go to wsj.com and find the dividend per share for each of the following firms.
- Microsoft
 - Apple
 - Coca-Cola
 - Facebook
- To find the dividend per share, enter the company's name in the search box on the home page. Which pays the highest dividend? Which has the highest dividend yield? Which does not pay a dividend? Why might a firm not

pay a dividend? Why would investors buy the stock of a firm that does not pay a dividend?

- D8.4 (Using stock data)** The following table lists the closing stock prices for three financial firms—Morgan Stanley, Citigroup Inc. and PNC Bank—for Friday, June 19, 2015. The table also includes the most recent dividends paid to shareholders by these firms.

	Morgan Stanley	Citigroup Inc.	PNC
Stock symbol	MS	C	PNC
Closing price	\$39.37	\$56.23	\$97.13
Latest dividend	\$0.15	\$0.05	\$0.51
Number of shares	100	100	100
Value of shares			
Total dividend			
Stock price increase	5 percent	5 percent	5 percent
New stock price			
Value of shares			
Capital gain			

Fill in the blank cells in the table by computing (a) the value of 100 shares of each company's stock, (b) total dividend payments for 100 shares of stock, and (c) assuming that each company's stock price increases by 5 percent, the new stock prices, the value of shares, and the increase in the value of each company's stock (capital gains). How will the price increases affect the total amount of dividends paid for each company's stock?

Appendix

Tools to Analyze Firms' Financial Information

LEARNING OBJECTIVE: Understand the concept of present value and the information contained on a firm's income statement and balance sheet.

As we saw in the chapter, modern firms are not just “black boxes” transforming inputs into output. The majority of business revenues and profits are earned by large corporations. Unlike founder-dominated firms, the typical large corporation is run by managers who generally do not own a controlling interest in the firm. Large firms raise funds from outside investors, and outside investors seek information on firms and the assurance that the managers of firms will act in the interests of the investors.

This chapter shows how corporations raise funds by issuing stocks and bonds. This appendix provides more detail to support that discussion. We begin by analyzing *present value* as a key concept in determining the prices of financial securities. We then provide greater information on *financial statements* issued by corporations, using Twitter as an example.

Using Present Value to Make Investment Decisions

Firms raise funds by selling equity (stock) and debt (bonds and loans) to investors and lenders. If you own shares of stock or a bond, you will receive payments in the form of dividends or coupons over a number of years. Most people value funds they already have more highly than funds they will receive some time in the future. For example, you would probably not trade \$1,000 you already have for \$1,000 you will not receive for one year. The longer you have to wait to receive a payment, the less value it will have for you. One thousand dollars you will not receive for two years is worth less to you than \$1,000 you will receive after one year. The value you give today to money you will receive in the future is called the future payment's **present value**. The present value of \$1,000 you will receive in one year will be less than \$1,000.

Why is the \$1,000 you will not receive for one year less valuable to you than the \$1,000 you already have? The most important reason is that if you have \$1,000 today, you can use that \$1,000 today. You can buy goods and services with the money and receive enjoyment from them. The \$1,000 you receive in one year does not have direct use to you now.

Also, prices will likely rise during the year you are waiting to receive your \$1,000. So, when you finally do receive the \$1,000 in one year, you will not be able to buy as much with it as you could with \$1,000 today. Finally, there is some risk that you will not receive the \$1,000 in one year. The risk may be very great if an unreliable friend borrows \$1,000 from you and vaguely promises to pay you back in one year. The risk may be very small if you lend money to the federal government by buying a U.S. Treasury bond. In either case, though, there is at least some risk that you will not receive the funds promised.

When someone lends money, the lender expects to be paid back both the amount of the loan and some additional interest. Say you are willing to lend \$1,000 today if you are paid back \$1,100 one year from now. In this case, you are charging $\$100/\$1,000 = 0.10$, or 10 percent interest on the funds you have loaned. Economists would say that you value \$1,000 today as equivalent to the \$1,100 to be received one year in the future.

Notice that \$1,100 can be written as $\$1,000(1 + 0.10)$. That is, the value of money received in the future is equal to the value of money in the present multiplied by 1 plus the interest rate, with the interest rate expressed as a decimal. Or:

$$\$1,100 = \$1,000(1 + 0.10).$$

Present value The value in today's dollars of funds to be paid or received in the future.

Notice, also, that if we divide both sides by $(1 + 0.10)$, we can rewrite this formula as:

$$\$1,000 = \frac{\$1,100}{(1 + 0.10)}.$$

The rewritten formula states that the present value is equal to the future value to be received in one year divided by 1 plus the interest rate. This formula is important because you can use it to convert any amount to be received in one year into its present value. Writing the formula generally, we have:

$$\text{Present value} = \frac{\text{Future value}_1}{(1 + i)}.$$

The present value of funds to be received in one year—Future value₁—can be calculated by dividing the amount of those funds to be received by 1 plus the interest rate. With an interest rate of 10 percent, the present value of \$1,000,000 to be received one year from now is:

$$\frac{\$1,000,000}{(1 + 0.10)} = \$909,090.91.$$

This formula allows us to calculate the value today of funds that will be received in one year. But financial securities such as stocks and bonds involve promises to pay funds over many years. Therefore, it would be useful if we could expand this formula to calculate the present value of funds to be received more than one year in the future.

Go back to the original example, where we assumed you were willing to loan out your \$1,000 for one year, provided that you received 10 percent interest. Suppose you are asked to lend the funds for two years and that you are promised 10 percent interest per year for each year of the loan. That is, you are lending \$1,000, which at 10 percent interest will grow to \$1,100 after one year, and you are agreeing to loan that \$1,100 for a second year at 10 percent interest. So, after two years, you will be paid back $\$1,100(1 + 0.10)$, or \$1,210. Or:

$$\$1,210 = \$1,000(1 + 0.10)(1 + 0.10),$$

or:

$$\$1,210 = \$1,000(1 + 0.10)^2.$$

This formula can also be rewritten as:

$$\$1,000 = \frac{\$1,210}{(1 + 0.10)^2}.$$

To put this formula in words, the \$1,210 you receive two years from now has a present value equal to \$1,210 divided by the quantity 1 plus the interest rate squared. If you agree to lend out your \$1,000 for three years at 10 percent interest, you will receive:

$$\$1,331 = \$1,000(1 + 0.10)^3.$$

Notice, again, that:

$$\$1,000 = \frac{\$1,331}{(1 + 0.10)^3}.$$

You can probably see a pattern here. We can generalize the concept to say that the present value of funds to be received n years in the future—whether n is 1, 20, or 85 does not matter—equals the amount of the funds to be received divided by the quantity 1 plus the interest rate raised to the n th power. For instance, with an interest rate of 10 percent, the value of \$1,000,000 to be received 25 years in the future is:

$$\text{Present value} = \frac{\$1,000,000}{(1 + 0.10)^{25}} = \$92,296.$$

Or, more generally:

$$\text{Present value} = \frac{\text{Future value}_n}{(1 + i)^n},$$

where Future value_n represents funds that will be received in n years.

How to Receive Your Contest Winnings

Suppose you win a contest and are given the choice of the following prizes:

Prize 1: \$50,000 to be received right away, with four additional payments of \$50,000 to be received each year for the next four years

Prize 2: \$175,000 to be received right away
Explain which prize you would choose and the basis for your decision.

Solving the Problem

Step 1: Review the material. This problem involves applying the concept of present value, so you may want to review the section “Using Present Value to Make Investment Decisions,” which begins on page 333.

Step 2: Explain the basis for choosing the prize. Unless you need cash immediately, you should choose the prize with the highest present value.

Step 3: Calculate the present value of each prize. Prize 2 consists of one payment of \$175,000 received right away, so its present value is \$175,000. Prize 1 consists of five payments spread out over time. To find the present value of the prize, we must find the present value of each of these payments and add them together. To calculate present value, we must use an interest rate. Let's assume an interest rate of 10 percent. In that case, the present value of Prize 1 is:

$$\begin{aligned} & \$50,000 + \frac{\$50,000}{(1 + 0.10)} + \frac{\$50,000}{(1 + 0.10)^2} + \frac{\$50,000}{(1 + 0.10)^3} + \frac{\$50,000}{(1 + 0.10)^4} \\ &= \$50,000 + \$45,454.55 + \$41,322.31 + \$37,565.74 + \$34,150.67 \\ &= \$208,493.27 \end{aligned}$$

Step 4: State your conclusion. Prize 1 has the greater present value, so you should choose it rather than Prize 2.

Your Turn: For more practice, do related problems 8A.6, 8A.7, 8A.8, and 8A.9 on page 340 at the end of this appendix.

Using Present Value to Calculate Bond Prices

Anyone who buys stocks or bonds is really buying a promise to receive certain payments—dividends in the case of stocks or coupons in the case of bonds. The price investors are willing to pay for a financial asset should be equal to the value of the payments they will receive as a result of owning the asset. Because most of the coupon or dividend payments will be received in the future, it is their present value that matters. We therefore have the following important idea: *The price of a financial asset should be equal to the present value of the payments to be received from owning that asset.*

Let's look at an example. Suppose that in 1988, General Electric issued a bond with an \$80 coupon that will mature in 2018. It is now 2016, and that bond has been bought and sold by investors many times. You are considering buying it. If you buy the bond, you will receive two years of coupon payments plus a final payment of the bond's principal, or face value, of \$1,000. Suppose, once again, that you need an interest rate of 10 percent to invest your funds. If the bond has a coupon of \$80, the present value of the payments you receive from owning the bond—and, therefore, the present value of the bond—will be:

$$\text{Present value} = \frac{\$80}{(1 + 0.10)} + \frac{\$80}{(1 + 0.10)^2} + \frac{\$1,000}{(1 + 0.10)^2} = \$965.29.$$

That is, the present value of the bond will equal the present value of the three payments you will receive during the two years you own the bond. You should, therefore, be willing to pay \$965.29 to own this bond and have the right to receive these payments from GE. This process of calculating present values of future payments is used to determine bond prices, with one qualification: The relevant interest rate used by investors in the bond market to calculate the present value and, therefore, the price of an existing bond is usually the coupon rate on comparable newly issued bonds. Therefore, the general formula for the price of a bond is:

$$\text{Bond price} = \frac{\text{Coupon}_1}{(1+i)} + \frac{\text{Coupon}_2}{(1+i)^2} + \dots + \frac{\text{Coupon}_n}{(1+i)^n} + \frac{\text{Face value}}{(1+i)^n},$$

where:

- Coupon_1 is the coupon payment to be received after one year.
- Coupon_2 is the coupon payment to be received after two years.
- Coupon_n is the coupon payment received in the year the bond matures.
- The ellipsis takes the place of the coupon payments—if any—received between the second year and the year when the bond matures.
- Face value is the amount that will be received when the bond matures.
- i is the interest rate on comparable newly issued bonds. MyEconLab Concept Check

Using Present Value to Calculate Stock Prices

When you own a firm's stock, you are legally entitled to your share of the firm's profits. Remember that the profits a firm pays out to its shareholders are called *dividends*. The price of a share of stock should equal the present value of the dividends investors expect to receive as a result of owning that stock. Therefore, the general formula for the price of a stock is:

$$\text{Stock price} = \frac{\text{Dividend}_1}{(1+i)} + \frac{\text{Dividend}_2}{(1+i)^2} + \dots$$

Notice that this formula looks very similar to the one we used to calculate the price of a bond, with a couple of important differences:

- First, unlike a bond, a share of stock has no maturity date, so we have to calculate the present value of an infinite number of dividend payments. It may seem that the stock's price must be infinite as well, but remember that dollars you don't receive for many years are worth very little today. For instance, a dividend payment of \$10 that will be received 40 years in the future is worth only a little more than \$0.20 today at a 10 percent interest rate.
- Second, you know with certainty the coupon payments you will receive from owning the bond because they are set when the bond is issued and cannot be changed. However, you don't know for sure what the dividend payments from owning a stock will be. How large a dividend payment you will receive depends on how profitable the company will be in the future.

Although it is possible to forecast the future profitability of a company, this cannot be done with perfect accuracy. To emphasize this point, some economists rewrite the basic stock price formula by adding a superscript e to each dividend term to emphasize that these are *expected* dividend payments. Because the future profitability of companies is often very difficult to forecast, it is not surprising that differences of opinion exist over what the price of a particular stock should be. Some investors will be optimistic about the future profitability of a company and will, therefore, believe that the company's stock should have a high price. Other investors might be pessimistic and believe that the company's stock should have a low price.

MyEconLab **Concept Check**

A Simple Formula for Calculating Stock Prices

It is possible to simplify the formula for determining the price of a stock. If we assume that dividends will grow at a constant rate, we get the following equation:

$$\text{Stock price} = \frac{\text{Dividend}}{(i - \text{Growth rate})}$$

In this equation, Dividend is the dividend expected to be received one year from now, and Growth rate is the rate at which those dividends are expected to grow. If a company pays a dividend of \$1 per share to be received one year from now and Growth rate is 10 percent, the company is expected to pay a dividend of \$1.10 the following year, \$1.21 the year after that, and so on.

Now suppose that IBM will pay a dividend of \$5 per share at the end of year, the consensus of investors is that these dividends will increase at a rate of 5 percent per year for the indefinite future, and the interest rate is 10 percent. Then the price of IBM's stock should be:

$$\text{Stock price} = \frac{\$5.00}{(0.10 - 0.05)} = \$100.00.$$

In recent years, investors have debated whether the high prices of the stocks of many high-tech firms, including Twitter, were justified, given that many of these companies had not made any profit yet and so had not paid any dividends. Is there any way that a rational investor would pay a high price for the stock of a company currently not earning profits? The formula for determining stock prices shows that it is possible, provided that the investor's assumptions are optimistic enough! For example, during 2015, one stock analyst predicted that Twitter would soon be earning \$1 per share of stock. That is, Twitter's total earnings divided by the number of shares of its stock outstanding would be \$1. Suppose Twitter pays out that \$1 in dividends and that the \$1 will grow rapidly over the years, by, say, 7 percent per year. Then the formula indicates that the price of Twitter's stock should be:

$$\text{Stock price} = \frac{\$1.00}{(0.10 - 0.07)} = \$33.33.$$

If you are sufficiently optimistic about the future prospects of a company, a high stock price can be justified even if the company is not currently earning a profit. But investors in stocks must be careful. Suppose investors decide that growth prospects for Twitter are only 4 percent per year instead of 7 percent because the firm turns out not to be as profitable as initially believed. Then our formula indicates that the price of Twitter's stock should be:

$$\text{Stock price} = \frac{\$1.00}{(0.10 - 0.04)} = \$16.67.$$

This price is only half the price determined assuming a more optimistic growth rate. We can conclude that investors use information about a firm's profitability and growth prospects to determine what the firm is worth.

Going Deeper into Financial Statements

Corporations disclose substantial information about their business operations and financial position to actual and potential investors. Some of this information meets the demands of participants in financial markets and of information-collection agencies, such as Moody's Investors Service, which develops credit ratings that help investors judge how risky corporate bonds are. Other information meets the reporting requirements of the U.S. Securities and Exchange Commission.

Key sources of information about a corporation's profitability and financial position are its principal financial statements—the *income statement* and the *balance sheet*. These important information sources were first introduced in the chapter. In the following section we go into more detail, using recent data for Twitter as an example.

Analyzing Income Statements

As discussed in the chapter, a firm's income statement summarizes its revenues, costs, and profit over a period of time. Figure 8A.1 shows Twitter's income statement for 2014.

Twitter's income statement presents the results of the company's operations during the year. Listed first are the revenues it earned, largely from selling advertising on its app, from January 1, 2014, to December 31, 2014: \$1,403 million. Listed next are Twitter's operating expenses, the most important of which is its *cost of revenue*—which is commonly known as *cost of sales* or *cost of goods sold*: \$446 million. Cost of revenue is the direct cost of producing the products sold, including in this case the salaries of the computer programmers Twitter hires to write the software for its app. Twitter also has substantial costs for researching and developing its products (\$692 million) and for advertising and marketing them (\$614 million). General and administrative expenses (\$190 million) include costs such as the salaries of top managers.

The difference between a firm's revenue and its costs is its *profit*. Profit shows up in several forms on an income statement. A firm's *operating income* is the difference between its revenue and its operating expenses. Most corporations, including Twitter, also have interest expenses and income from investments, such as government and corporate bonds. In this case, Twitter paid \$39 million more in interest expenses than it earned on its investments. Because its costs were greater than its revenue, Twitter's *income before taxes* was a loss (a loss in financial statements is indicated by the use of parenthesis) of \$578 million. The federal government taxes the profits of corporations, but because Twitter experienced a

Figure 8A.1 Twitter's Income Statement for 2014

Twitter's income statement shows the company's revenue, costs, and profit for 2014. The difference between its revenue (\$1,403 million) and its operating expenses (\$1,942 million) is its operating income (a loss of \$539 million). Most corporations also have interest expenses and income from investments, such as government and corporate bonds. In this case, Twitter

paid \$39 million more in interest expenses than it earned on its investments, so its *income before taxes* was a loss of \$578 million. Twitter had a net loss, or accounting loss, of \$578 million for the year.

Note: Negative values in the figure are shown in parentheses.

loss in 2014, it paid no taxes. Therefore, Twitter's *net income* after taxes was also a loss of \$578 million. The fact that Twitter could experience a loss while still having a high stock price is an indication that investors were expecting Twitter to earn significant profits in the future. The net income that firms report on their income statements is referred to as their after-tax *accounting profit*.

Analyzing Balance Sheets

As discussed in the chapter, while a firm's income statement reports the firm's activities for a period of time, a firm's balance sheet summarizes its financial position on a particular day, usually the end of a quarter or year. To understand how a balance sheet is organized, first recall that an asset is anything of value that the firm owns, and a liability is a debt or an obligation that the firm owes. Subtracting the value of a firm's liabilities from the value of its assets leaves its *net worth*. Because a corporation's stockholders are its owners, net worth is often listed as **stockholders' equity** on a balance sheet. Using these definitions, we can state the balance sheet equation (also called the basic accounting equation) as follows:

$$\text{Assets} - \text{Liabilities} = \text{Stockholders' Equity},$$

or:

$$\text{Assets} = \text{Liabilities} + \text{Stockholders' Equity}.$$

This equation tells us that the value of a firm's assets must equal the value of its liabilities plus the value of stockholders' equity. An important accounting convention dating back to the beginning of modern bookkeeping in fifteenth-century Italy holds that balance sheets should list assets on the left side and liabilities and net worth, or stockholders' equity, on the right side. Notice that this means that *the value of the left side of the balance sheet must always equal the value of the right side*. Figure 8A.2 shows Twitter's balance sheet as of December 31, 2014.

A couple of the entries on the asset side of the balance sheet may be unfamiliar: *Current assets* are assets that the firm could convert into cash quickly, such as the balance in its checking account or its accounts receivable, which is money currently owed to the firm for products that have been delivered but not yet paid for. *Goodwill* represents the difference between the purchase price of a company and the market value of its assets. It represents the ability of a business to earn an economic profit from its assets. For example, if you buy a restaurant that is located on a busy intersection and you employ a chef with a reputation for preparing delicious food, you may pay more than the market value of the tables, chairs, ovens, and other assets. This additional amount you pay will be entered on the asset side of your balance sheet as goodwill.

Current liabilities are short-term debts such as accounts payable, which is money owed to suppliers for goods received but not yet paid for, or bank loans that will be paid back in less than one year. Long-term bank loans, the value of outstanding corporate bonds, and other long-term debts are *long-term liabilities*.

Property and equipment	557	Long-term liabilities	1,563
Goodwill	623	Total liabilities	1,957
Other assets	147	Stockholders' equity	3,626
Total assets	\$5,583	Total liabilities and stockholders' equity	\$5,583

Figure 8A.2

Twitter's Balance Sheet as of December 31, 2014

Corporations list their assets on the left of their balance sheets and their liabilities on the right. The difference between the value of a firm's assets and the value of its liabilities equals the net worth of the firm, or stockholders' equity. Stockholders' equity is listed on the right side of the balance sheet. Therefore, the value of the left side of the balance sheet must always equal the value of the right side.

President Obama, Nike, and Free Trade

Where were your shoes made? If you answer either China or Vietnam, you are likely to be correct. But if you lived in the United States during the 1930s, you would have answered “right here.” At that time, there were nearly 2,000 shoe factories in the United States, employing more than 275,000 workers. Today, 99 percent of shoes sold in the United States are made overseas, and U.S. shoe factories employ fewer than 15,000 workers. Nike illustrates the evolution of today’s U.S. shoe industry. Headquartered in Beaverton, Oregon, Nike employs about 26,000 people in the United States, but most work in administration, sales, and research and development. Nike has contracts with foreign shoe firms that employ nearly 1 million workers to manufacture Nike shoes in factories in China, Vietnam, and Indonesia.

Would U.S. consumers and workers be better off if the federal government banned imports of shoes, so all shoes bought in the United States were made here? President Barack Obama would answer “no.” In 2015, he visited Nike’s headquarters to push for Congressional passage of the *Trans-Pacific Partnership (TPP)*, an agreement between the United States and 11 other countries, including Canada, Japan, Mexico, and Vietnam. The TPP is meant to reduce trade barriers among

these countries. The Obama administration argued that the TPP will “unlock opportunities for American manufacturers, workers, service providers, farmers, and ranchers—to support job creation and wage growth.”

Critics argued that the TPP will further expose U.S. firms and workers to competition from foreign firms where the average wage is less than \$5 per day. Although the TPP includes provisions to enforce environmental standards in foreign factories, some environmentalists are skeptical that the provisions will be enforced. The AFL-CIO, a labor union organization, argued, “Unfortunately, it is becoming clear the TPP will not create jobs, protect the environment and ensure safe imports.”

Does eliminating restrictions on international trade help workers and consumers in the United States, or does it hurt them? In this chapter, we will analyze this and other important questions related to international trade.

Economics in Your Life

Did You Know There Is a Tariff on Running Shoes?

Politicians often support policies that restrict imports from foreign countries because they want to convince people to vote for them. The workers in the industries these restrictions protect are likely to vote for the politicians because they believe the restrictions will save their jobs. But most people do *not* work in industries that are protected from foreign competition by trade restrictions. The federal government imposes a tariff, or tax, on imports of most shoes into the United States. As a result, U.S. consumers pay higher prices for shoes. But very few people in the United States today are employed in shoe factories. Why, then, does the federal government have a tariff on shoes, and why are so few people aware that it exists? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 367** at the end of this chapter.

Trade is simply the act of buying or selling. Is there a difference between trade that takes place within a country and international trade? Within the United States, domestic trade makes it possible for consumers in Ohio to eat salmon caught in Alaska and for consumers in Montana to drive cars built in Michigan or Kentucky. Similarly, international trade makes it possible for consumers in the United States to drink wine from France and use Blu-ray players from Japan. One significant difference between domestic trade and international trade is that international trade is more controversial. At one time, nearly all the televisions, shoes, clothing, and toys bought in the United States were also produced here. Today, firms in other countries produce most of these goods. This shift has benefited U.S. consumers because foreign-made goods have lower prices or higher quality than the U.S.-made goods they have replaced. At the same time, though, many U.S. firms that produced these goods have gone out of business, and their workers have had to find other jobs. Not surprisingly, opinion polls show that many Americans favor reducing international trade because they believe doing so will preserve jobs in the United States. But is this belief accurate?

We can use the tools of demand and supply to analyze markets for internationally traded goods and services. We have seen that trade in general—whether within a country or between countries—is based on the principle of comparative advantage (see Chapter 2). In this chapter, we look more closely at the role of comparative advantage in international trade. We also use the concepts of consumer surplus, producer surplus, and deadweight loss (see Chapter 4) to analyze government policies that interfere with trade. With this background, we can return to the political debate over whether the United States benefits from international trade. We begin by looking at how large a role international trade plays in the U.S. economy.

9.1

The United States in the International Economy

LEARNING OBJECTIVE: Discuss the role of international trade in the U.S. economy.

International trade has grown tremendously over the past 50 years due primarily to these three factors: The decreasing costs of shipping products around the world, the spread of inexpensive and reliable communications, and changes in government policies. Firms can use large container ships to send their products across oceans at low cost. Businesspeople today can travel to Europe or Asia, using fast, inexpensive, and reliable air transportation. The Internet, cellphones, and text messaging allow managers to communicate instantaneously and at a very low cost with customers and suppliers around the world. These and other improvements in transportation and communication have created an integrated global marketplace that earlier generations of businesspeople could only dream of.

Over the past 50 years, many governments have changed policies to facilitate international trade. For example, tariff rates have fallen. A **tariff** is a tax imposed by a government on *imports* into a country. **Imports** are goods and services bought domestically but produced in other countries. In the 1930s, the United States charged an average tariff rate above 50 percent. Today, the rate is less than 1.5 percent. In North America, most tariffs between Canada, Mexico, and the United States were eliminated following the passage of the North American Free Trade Agreement (NAFTA) in 1994. In Europe, 29 countries have formed the European Union, which has eliminated all tariffs among member countries, greatly increasing both imports and **exports**, which are goods and services produced domestically but sold in other countries. In 2015, the Obama administration concluded negotiating the Trans-Pacific Partnership (TPP), which is an agreement between the United States and 11 other countries around the Pacific Ocean, including Canada, Japan, Mexico, and Vietnam. The TPP will eliminate most tariffs between these countries, which together account for nearly 40 percent of world production of goods and services.

The Importance of Trade to the U.S. Economy

U.S. consumers buy increasing quantities of goods and services produced in other countries. At the same time, U.S. businesses sell increasing quantities of goods and services to consumers in other countries. Figure 9.1 shows that since 1970, with the exception of the period of the severe recession of 2007–2009, both exports and imports have been increasing as a fraction of U.S. gross domestic product (GDP). Recall that GDP is the value of all the final goods and services produced in a country during a year. In 1970, exports and imports were both less than 6 percent of U.S. GDP. In 2014, exports were about 13 percent of GDP, and imports were about 17 percent.

Not all sectors of the U.S. economy are affected equally by international trade. For example, although it’s difficult to import or export some services, such as haircuts and appendectomies, a large percentage of U.S. agricultural production is exported. Each year, the United States exports about 50 percent of its wheat and rice crops and 20 percent of its corn crop.

Many U.S. manufacturing industries also depend on trade. About 20 percent of U.S. manufacturing jobs depend directly or indirectly on exports. In some industries, such as pharmaceutical drugs, the products are directly exported. In other industries, such as steel, the products are used to make other products, such as bulldozers or machine tools, that are then exported. In all, about two-thirds of U.S. manufacturing industries depend on exports for at least 10 percent of jobs.

Would New Balance Be Helped or Hurt By the Trans-Pacific Partnership?

Founded in 1906, New Balance Athletic Shoe, which is headquartered in Boston, Massachusetts, seems to have bucked the long-run trend of shoe production leaving the United States.

New Balance operates two factories in Massachusetts and three in Maine, employing about 1,400 workers to manufacture shoes. Many people think of New Balance as the “Made in America” shoe company, and it is the only company making significant quantities of shoes in the United States. It labels its shoes as “Made in the USA” when they contain at least 70 percent U.S.-made parts.

New Balance Athletic Shoe assembles more than 4 million pairs of athletic shoes a year in its Massachusetts and Maine factories.

Not only does New Balance label shoes as “Made in the USA” that may have a significant amount of foreign-made parts, but the firm also notes on its Web site that its U.S. production is only a “limited portion” of its U.S. sales. Although New Balance does manufacture shoes in the United States, it also sells shoes made in factories in other countries. Those foreign factories produce about 75 percent of the shoes New Balance sells in the United States. The New Balance factories in New England primarily assemble shoes from soles, tops, and other pieces that are manufactured by its suppliers, some of which are in the United States and some of which are overseas.

At the time policymakers debated the Trans-Pacific Partnership (TPP), the United States imposed tariffs of 25 to 67.5 percent on the value of imported shoes and shoe parts. Implementation of the TPP will eliminate tariffs on shoe imports from Vietnam and Malaysia, which are major exporters of shoes to the United States,

but those tariffs will remain on imports from China, where the majority of New Balance shoes sold in the United States are made. Nike, New Balance’s key competitor, imports the majority of its shoes from Vietnam, so it will receive a larger benefit from the passage of the TPP than New Balance will.

New Balance, then, was in a somewhat complicated situation as the debate over the TPP took place. Eliminating the tariff on shoes imported from TPP countries will hurt New Balance by lowering the prices on some of the imported shoes sold by other companies that compete with New Balance’s U.S.-produced shoes. But New Balance will benefit because it will be able to sell the shoes it imports from TPP countries at a lower price, and because the cost of the shoe parts it imports from TPP countries for use in its U.S. factories will also decline. Not surprisingly, the company did not voice a strong position either for or against the TPP. A spokesperson for the company was quoted as saying, “We’ve had productive discussions with the Obama administration regarding TPP, and we’re hopeful that the final agreement will reflect those discussions and will allow us to continue to thrive as a domestic producer.”

Today, few U.S.-based manufacturing firms make their products exclusively in the United States out of entirely U.S.-made parts. As a result, the positions of these firms on reducing barriers to international trade can be difficult to predict.

U.S. International Trade in a World Context

The United States is the second-largest exporter in the world, just behind China, as Figure 9.2 illustrates. Six of the other seven leading exporting countries are also high-income countries. Although China is still a relatively low-income country, the rapid growth of the Chinese economy over the past 35 years has resulted in its becoming the largest exporter. Three of the top exporting countries are in East Asia, four are in Western Europe, and one is in North America.

Figure 9.3 shows that international trade is less important to the United States than it is to many other countries, with imports and exports being lower percentages of GDP. In some smaller countries, such as Belgium and the Netherlands, imports and exports make up more than half of GDP. In the larger European economies, imports and exports make up one-quarter to one-half of GDP.

9.2 Comparative Advantage in International Trade

LEARNING OBJECTIVE: Explain the difference between comparative advantage and absolute advantage in international trade.

Why have businesses around the world increasingly looked for markets in other countries? Why have consumers increasingly purchased goods and services made in other countries? People trade for one reason: Trade makes them better off. Whenever a buyer and seller agree to a sale, they must both believe they are better off; otherwise, there would be no sale. This outcome must hold whether the buyer and seller live in the same city or in different countries. As we will see, governments are more likely to interfere with international trade than they are with domestic trade, but the reasons for the interference are more political than economic.

A Brief Review of Comparative Advantage

Recall that **comparative advantage** is the ability of an individual, a firm, or a country to produce a good or service at a lower opportunity cost than competitors. **Opportunity cost** is the highest-valued alternative that must be given up to engage in an activity. People, firms, and countries specialize in economic activities in which they have a comparative advantage. In trading, we benefit from the comparative advantage of other people (or firms or countries), and they benefit from our comparative advantage.

A good way to think of comparative advantage is to recall the example of you and your neighbor picking fruit (see Chapter 2). Your neighbor is better at picking both apples and

cherries than you are. Why, then, doesn't your neighbor pick both types of fruit? Because the opportunity cost to your neighbor of picking her own apples is very high: She is a particularly skilled cherry picker, and every hour spent picking apples is an hour taken away from picking cherries. You can pick apples at a much lower opportunity cost than your neighbor, so you have a comparative advantage in picking apples. Your neighbor can pick cherries at a much lower opportunity cost than you can, so she has a comparative advantage in picking cherries. Your neighbor is better off specializing in picking cherries, and you are better off specializing in picking apples. You can then trade some of your apples for some of your neighbor's cherries, and both of you will end up with more of each fruit. (If you have trouble following the point here, refer back to Tables 2.1 and 2.2.)

MyEconLab Concept Check

Comparative Advantage and Absolute Advantage

The principle of comparative advantage can explain why people pursue different occupations. It can also explain why countries produce different goods and services. International trade involves many countries importing and exporting many different goods and services. Countries are better off if they specialize in producing the goods for which they have a comparative advantage. They can then trade for the goods for which other countries have a comparative advantage.

We can illustrate why specializing on the basis of comparative advantage makes countries better off with a simple example involving just two countries and two products. Suppose the United States and Japan produce only smartwatches and tablet computers, like Apple's iPad or Samsung's Galaxy Tab. Assume that each country uses only labor to produce each good and that Japanese and U.S. smartwatches and tablets are exactly the same. Table 9.1 shows how much each country can produce of each good with one hour of labor.

Notice that Japanese workers are more productive than U.S. workers in making both goods. In one hour, Japanese workers can make six times as many smartwatches and one and one-half times as many tablets as U.S. workers. Japan has an *absolute advantage* over the United States in producing both goods. **Absolute advantage** is the ability to produce more of a good or service than competitors when using the same amount of resources. In this case, Japan can produce more of both goods using the same amount of labor as the United States.

It might seem at first that Japan has nothing to gain from trading with the United States because it has an absolute advantage in producing both goods. However, Japan should specialize and produce only smartwatches and obtain the tablets it needs by exporting smartwatches to the United States in exchange for tablets. The reason Japan benefits from trade is that although it has an *absolute advantage* in the production of both goods, it has a *comparative advantage* only in the production of smartwatches. The United States has a comparative advantage in the production of tablets.

If it seems contrary to common sense that Japan should import tablets from the United States even though Japan can produce more of them per hour of labor, think about the opportunity cost to each country of producing each good. If Japan wants to produce more tablets, it has to switch labor away from smartwatch production. Every hour of labor switched from producing smartwatches to producing tablets increases tablet production by 6 and reduces smartwatch production by 12. Japan has to give up 12 smartwatches for every 6 tablets it produces. Therefore, the opportunity cost to Japan of producing one more tablet is $12/6$, or 2 smartwatches.

If the United States switches one hour of labor from smartwatches to tablets, production of smartwatches falls by 2 and production of tablets rises by 4.

Absolute advantage The ability to produce more of a good or service than competitors when using the same amount of resources.

Table 9.1
An Example of Japanese Workers Being More Productive Than American Workers

	Output per Hour of Work	
	Smartwatches	Tablets
Japan	12	6
United States	2	4

	Opportunity Costs	
	Smartwatches	Tablets
Japan	0.5 tablet	2 smartwatches
United States	2 tablets	0.5 smartwatch

Therefore, the opportunity cost to the United States of producing one more tablet is 2/4, or 0.5 smartwatch. The United States has a lower opportunity cost of producing tablets and, therefore, has a comparative advantage in making this product. By similar reasoning, we can see that Japan has a comparative advantage in producing smartwatches. Table 9.2 summarizes the opportunity cost each country faces in producing these goods.

Table 9.2

The Opportunity Costs of Producing Smartwatches and Tablets

The table shows the opportunity cost each country faces in producing smartwatches and tablets. For example, the entry in the first row and second column shows that Japan must give up 2 smartwatches for every tablet it produces.

9.3

How Countries Gain from International Trade

LEARNING OBJECTIVE: Explain how countries gain from international trade.

Can Japan really gain from producing only smartwatches and trading with the United States for tablets? To see that it can, assume at first that Japan and the United States do not trade with each other. A situation in which a country does not trade with other countries is called **autarky**. Assume that in autarky, each country has 1,000 hours of labor available to produce the two goods, and each country produces the quantities of the two goods shown in Table 9.3. Because there is no trade, these quantities also represent consumption of the two goods in each country.

Autarky A situation in which a country does not trade with other countries.

Increasing Consumption through Trade

Suppose now that Japan and the United States begin to trade with each other. The **terms of trade** is the ratio at which a country can trade its exports for imports from other countries. For simplicity, let's assume that the terms of trade end up with Japan and the United States being willing to trade one smartwatch for one tablet.

Terms of trade The ratio at which a country can trade its exports for imports from other countries.

Once trade has begun, the United States and Japan can exchange tablets for smartwatches or smartwatches for tablets. For example, if Japan specializes by using all 1,000 available hours of labor to produce smartwatches, it will be able to produce 12,000 smartwatches. It then could export 1,500 smartwatches to the United States in exchange for 1,500 tablets. (Remember that we are assuming the terms of trade are 1 smartwatch for 1 tablet.) Japan ends up with 10,500 smartwatches and 1,500 tablets. Compared with the situation before trade, Japan has the same number of tablets but 1,500 more smartwatches. If the United States specializes in producing tablets, it will be able to produce 4,000 tablets. It could then export 1,500 tablets to Japan in exchange for 1,500 smartwatches. The United States ends up with 2,500 tablets and 1,500 smartwatches. Compared with the situation before trade, the United States has the same number of smartwatches but 1,500 more tablets. Trade has allowed both countries to increase the quantities of goods consumed. Table 9.4 summarizes the gains from trade for the United States and Japan.

By trading, Japan and the United States are able to consume more than they could without trade. This outcome is possible because world production of both goods increases after trade. (In this example, our "world" consists of just the United States and Japan.)

Why does total production of smartwatches and tablets increase when the United States specializes in producing tablets and Japan specializes in producing smartwatches?

	Production and Consumption	
	Smartwatches	Tablets
Japan	9,000	1,500
United States	1,500	1,000

Table 9.3

Production without Trade

United States	0	4,000	Import 1,500	Export 1,500	1,500	2,500

With trade, the United States and Japan specialize in the good they have a comparative advantage in producing . . .

. . . and export some of that good in exchange for the good the other country has a comparative advantage in producing.

Gains from Trade		
Increased Consumption		
Japan	1,500 Smartwatches	} The increased consumption made possible by trade represents the gains from trade.
United States	1,500 Tablets	

A domestic analogy helps to answer this question: If a company shifts production from an old factory to a more efficient modern factory, its output will increase. The same thing happens in our example. Producing tablets in Japan and smartwatches in the United States is inefficient. Shifting production to the more efficient country—the one with the comparative advantage—increases total production. The key point is: *Countries gain from specializing in producing goods in which they have a comparative advantage and trading for goods in which other countries have a comparative advantage.* MyEconLab Concept Check

The Gains from Trade

The first discussion of comparative advantage appears in *On the Principles of Political Economy and Taxation*, a book written by the British economist David Ricardo in 1817. Ricardo provided a famous example of the gains from trade, using wine and cloth production in Portugal and England. The following table is adapted from Ricardo’s example, with cloth measured in sheets and wine measured in kegs:

	Output per Year of Labor	
	Cloth	Wine
Portugal	100	150
England	90	60

- a. Explain which country has an absolute advantage in the production of each good.

- b. Explain which country has a comparative advantage in the production of each good.
- c. Suppose that Portugal and England currently do not trade with each other. Each country has 1,000 workers, so each has 1,000 years of labor time to use in producing cloth and wine, and the countries are currently producing the amounts of each good shown in the following table:

	Cloth	Wine
Portugal	18,000	123,000
England	63,000	18,000

Show that Portugal and England can both gain from trade. Assume that the terms of trade are that one sheet of cloth can be traded for one keg of wine.

Solving the Problem

- Step 1: Review the chapter material.** This problem is about absolute and comparative advantage and the gains from trade, so you may want to review the sections “Comparative Advantage in International Trade,” which begins on page 347, and “How Countries Gain from International Trade,” which begins on page 349.
- Step 2: Answer part (a) by determining which country has an absolute advantage.** Remember that a country has an absolute advantage over another country when it can produce more of a good using the same resources. The first table in the problem shows that Portugal can produce more cloth *and* more wine with one year’s worth of labor than can England. Therefore, Portugal has an absolute advantage in the production of both goods, and England does not have an absolute advantage in the production of either good.
- Step 3: Answer part (b) by determining which country has a comparative advantage.** A country has a comparative advantage when it can produce a good at a lower opportunity cost. To produce 100 sheets of cloth, Portugal must give up producing 150 kegs of wine. Therefore, Portugal’s opportunity cost of producing 1 sheet of cloth is $150/100$, or 1.5 kegs of wine. England has to give up producing 60 kegs of wine to produce 90 sheets of cloth, so its opportunity cost of producing 1 sheet of cloth is $60/90$, or 0.67 keg of wine. The opportunity costs of producing wine can be calculated in the same way. The following table shows the opportunity cost to Portugal and England of producing each good.

	Opportunity Costs	
	Cloth	Wine
Portugal	1.5 kegs of wine	0.67 sheet of cloth
England	0.67 keg of wine	1.5 sheets of cloth

Portugal has a comparative advantage in wine because its opportunity cost is lower. England has a comparative advantage in cloth because its opportunity cost is lower.

- Step 4: Answer part (c) by showing that both countries can benefit from trade.** By now it should be clear that both countries will be better off if they specialize in producing the good for which they have a comparative advantage and trade for the other good. The following table is very similar to Table 9.4 and shows one example of trade making both countries better off. (To test your understanding, construct another example.)

Without Trade						
	Production and Consumption					
	Cloth			Wine		
Portugal	18,000			123,000		
England	63,000			18,000		

With Trade

	Cloth	Wine	Cloth	Wine	Cloth	Wine
Portugal	0	150,000	Import 18,000	Export 18,000	18,000	132,000
England	90,000	0	Export 18,000	Import 18,000	72,000	18,000

Portugal	9,000 wine
England	9,000 cloth

Why Don't We See Complete Specialization?

In our example of two countries producing only two products, each country specializes in producing one of the goods. In the real world, many goods and services are produced in more than one country. For example, the United States, Japan, Germany, Canada, Mexico, India, China, and other countries produce automobiles. We do not see complete specialization in the real world for three main reasons:

- **Not all goods and services are traded internationally.** For example, even if Japan had a comparative advantage in the production of medical services, it would be difficult for Japan to specialize in producing medical services and then export them. There is no easy way for U.S. patients who need appendectomies to receive them from surgeons in Japan.
- **Production of most goods involves increasing opportunity costs.** Recall that production of most goods involves increasing opportunity costs (see Chapter 2). In our example, if the United States devotes more workers to producing tablets, the opportunity cost of producing more tablets will increase. At some point, the opportunity cost of producing tablets in the United States may rise to the level of the opportunity cost of producing tablets in Japan. When that happens, international trade will no longer push the United States further toward specialization. The same will be true of Japan: The increasing opportunity cost of producing smartwatches will cause Japan to stop short of complete specialization.
- **Tastes for products differ.** Most products are *differentiated*. Smartwatches, tablets, cars, and televisions—to name just a few products—come with a wide variety of features. When buying automobiles, some people look for reliability and fuel efficiency, others look for room to carry seven passengers, and still others want styling and high performance. So, some car buyers prefer Toyota Prius hybrids, and some prefer Chevy Suburbans, and others prefer BMWs. As a result, Japan, the United States, and Germany may each have a comparative advantage in producing different types of automobiles.

MyEconLab Concept Check

Does Anyone Lose as a Result of International Trade?

In our smartwatch and tablet example, consumption increases in both the United States and Japan as a result of trade. Everyone gains, and no one loses. Or do they? In our example, we referred repeatedly to “Japan” or the “United States” producing smartwatches or tablets. But countries do not produce goods—firms do. In a world without trade, there would be smartwatch and tablet firms in both Japan and the United States. In a world with trade, there would be only Japanese smartwatch firms and U.S. tablet firms. Japanese tablet firms and U.S. smartwatch firms would close. Overall, total employment would not change, and production would increase as a result of trade. Nevertheless, the owners of Japanese tablet firms, the owners of U.S. smartwatch firms, and the people who work for them are worse off as a result of trade. The losers from trade are likely to do their best to convince the Japanese and U.S. governments to interfere with trade by barring imports of the competing products from the other country or by imposing high tariffs on them.

MyEconLab Concept Check

Don't Let This Happen to You

Remember That Trade Creates Both Winners and Losers

The following statement is from a Federal Reserve publication: “Trade is a win–win situation for all countries that participate.” People sometimes interpret statements like this to mean that there are no losers from international trade. But notice that the statement refers to *countries*, not individuals. When countries participate in trade, they make their consumers better off by increasing the quantity of goods and services available to them. As we have seen, however, expanding trade eliminates the jobs of workers employed at companies that are less efficient than foreign companies. Trade also creates new jobs at companies that export products to foreign markets. It may be difficult, though, for workers who lose their jobs because of trade

to easily find others. That is why in the United States the federal government uses the Trade Adjustment Assistance program to provide funds for workers who have lost their jobs due to international trade. Qualified unemployed workers can use these funds to pay for retraining, searching for new jobs, or relocating to areas where new jobs are available. This program—and similar programs in other countries—recognizes that there are losers from international trade as well as winners.

Where Does Comparative Advantage Come From?

Among the main sources of comparative advantage are the following:

- **Climate and natural resources.** This source of comparative advantage is the most obvious. Because of geology, Saudi Arabia has a comparative advantage in the production of oil. Because of climate and soil conditions, Costa Rica has a comparative advantage in the production of bananas, and the United States has a comparative advantage in the production of wheat.
- **Relative abundance of labor and capital.** Some countries, such as the United States, have many highly skilled workers and a great deal of machinery. Other countries, such as China, have many unskilled workers and relatively little machinery. As a result, the United States has a comparative advantage in the production of goods that require highly skilled workers or sophisticated machinery, such as aircraft and computer software. China has a comparative advantage in the production of goods, such as tools, clothing, and children’s toys, that require unskilled workers and small amounts of simple machinery.
- **Technology.** Broadly defined, *technology* is the process firms use to turn inputs into goods and services. At any given time, firms in different countries do not all have access to the same technologies. In part, this difference is a result of past investments countries have made in higher education or in supporting research and development. Some countries are strong in *product technologies*, which involve the ability to develop new products. For example, firms in the United States have pioneered the development of such products as radios, televisions, digital computers, airliners, medical equipment, and many prescription drugs. Other countries are strong in *process technologies*, which involve the ability to improve the processes used to make existing products. For example, Japanese-based firms, such as Toyota and Honda, have succeeded by greatly improving the processes for designing and manufacturing automobiles.
- **External economies.** It is difficult to explain the location of some industries on the basis of climate, natural resources, the relative abundance of labor and capital, or technology. For example, why does southern California have a comparative advantage in making movies or Switzerland in making watches or New York in providing financial services? The answer is that once an industry becomes established in an area, firms located in that area gain advantages over firms located elsewhere.

External economies Reductions in a firm's costs that result from an increase in the size of an industry.

The advantages include the availability of skilled workers, the opportunity to interact with other firms in the same industry, and proximity to suppliers. These advantages result in lower costs to firms located in the area. Because these lower costs result from increases in the size of the industry in an area, economists refer to them as **external economies**.

Comparative Advantage over Time: The Rise and Fall—and Rise—of the U.S. Consumer Electronics Industry

A country may develop a comparative advantage in the production of a good, and then, as time passes and circumstances change, the country may lose its comparative advantage in producing that good and develop a comparative advantage in producing other goods. For several decades, the United States had a comparative advantage in the production of consumer electronic goods, such as televisions, radios, and stereos. The comparative advantage of the United States in these products was based on having developed most of the underlying technology, having the most modern factories, and having a skilled and experienced workforce. Gradually, however, other countries, particularly Japan, gained access to the technology, built modern factories, and developed skilled workforces. As mentioned earlier, Japanese firms have excelled in process technologies, which involve the ability to improve the processes used to make existing products. By the 1970s and 1980s, Japanese firms were able to produce many consumer electronic goods more cheaply and with higher quality than could U.S. firms. Japanese firms Sony, Panasonic, and Pioneer replaced U.S. firms Magnavox, Zenith, and RCA as world leaders in consumer electronics.

By the mid-2000s, however, as the technology underlying consumer electronics had evolved, comparative advantage had shifted again, and several U.S. firms had surged ahead of their Japanese competitors. For example, Apple had developed the iPod, iPhone, iPad, and Apple Watch; Linksys, a division of Cisco Systems, took the lead in home wireless networking technology; and TiVo pioneered the digital video recorder (DVR). As pictures and music converted to digital data, process technologies became less important than the ability to design and develop new products. These new consumer electronic products required skills similar to those in computer design and software writing, where the United States had long maintained a comparative advantage. Although for the most part these firms did not manufacture within the United States the products they designed and marketed, even that may be changing. Apple has begun assembling its Mac Pro computer in the United States. Foxconn, a Taiwanese electronics manufacturer, also announced plans to build factories in the United States that will produce robots and displays for electronic devices.

Once a country has lost its comparative advantage in producing a good, its income will be higher and its economy will be more efficient if it switches from producing the good to importing it, as the United States did when it switched from producing televisions to importing them. As we will see in the next section, however, there is often political pressure on governments to attempt to preserve industries that have lost their comparative advantage.

9.4 Government Policies That Restrict International Trade

LEARNING OBJECTIVE: Analyze the economic effects of government policies that restrict international trade.

Free trade Trade between countries that is without government restrictions.

Free trade, or trade between countries without government restrictions, makes consumers better off. We can expand on this idea by using the concepts of consumer surplus and producer surplus (see Chapter 4, Section 4.1). Figure 9.4 shows the market in the United States for the biofuel ethanol, which can be used as a substitute for gasoline. The figure shows the situation of autarky, where the United States does not trade with other countries. The equilibrium price of ethanol is \$2.00 per gallon, and the

MyEconLab Animation

Figure 9.4

The U.S. Market for Ethanol under Autarky

This figure shows the market for ethanol in the United States, assuming autarky, where the United States does not trade with other countries. The equilibrium price of ethanol is \$2.00 per gallon, and the equilibrium quantity is 6.0 billion gallons per year. The blue area represents consumer surplus, and the red area represents producer surplus.

equilibrium quantity is 6.0 billion gallons per year. The blue area represents consumer surplus, and the red area represents producer surplus.

Now suppose that the United States begins importing ethanol from Brazil and other countries that produce ethanol for \$1.00 per gallon. Because the world market for ethanol is large, we will assume that the United States can buy as much ethanol as it wants without causing the *world price* of \$1.00 per gallon to rise. Therefore, once imports of ethanol are allowed into the United States, U.S. firms will not be able to sell ethanol at prices higher than the world price of \$1.00, and the U.S. price will become equal to the world price.

Figure 9.5 shows the result of allowing imports of ethanol into the United States. With the price lowered from \$2.00 to \$1.00, U.S. consumers increase their purchases from 6.0 billion gallons to 9.0 billion gallons. Equilibrium moves from point *F* to point *G*. In the new equilibrium, U.S. producers have reduced the quantity of ethanol they supply from 6.0 billion gallons to 3.0 billion gallons. Imports will equal 6.0 billion gallons, which is the difference between U.S. consumption and U.S. production.

Under autarky, consumer surplus would be area *A* in Figure 9.5. With imports, the reduction in price increases consumer surplus, so it is now equal to the sum of areas *A*, *B*, *C*, and *D*. Although the lower price increases consumer surplus, it reduces producer surplus. Under autarky, producer surplus was equal to the sum of areas *B* and *E*. With imports, it is equal to only area *E*. Recall that economic surplus equals the sum of consumer surplus and producer surplus. Moving from autarky to allowing imports increases economic surplus in the United States by an amount equal to the sum of areas *C* and *D*.

We can conclude that international trade helps consumers but hurts firms that are less efficient than foreign competitors. As a result, these firms and their workers are often strong supporters of government policies that restrict trade. These policies usually take one of two forms: (1) *tariffs*, and (2) *quotas* and *voluntary export restraints*.

Tariffs

The most common interferences with trade are *tariffs*, which are taxes imposed by a government on goods imported into the country. Like any other tax, a tariff increases the cost of selling a good. Figure 9.6 shows the effect of a tariff of \$0.50 per gallon on ethanol imports into the United States. The \$0.50 tariff raises the price of ethanol in the United States from the world price of \$1.00 per gallon to \$1.50 per gallon. At this

MyEconLab Animation

Figure 9.5

The Effect of Imports on the U.S. Ethanol Market

When imports are allowed into the United States, the price of ethanol falls from \$2.00 to \$1.00. U.S. consumers increase their purchases from 6.0 billion gallons to 9.0 billion gallons. Equilibrium moves from point F to point G. U.S. producers reduce the quantity of ethanol they supply from 6.0 billion gallons to 3.0 billion gallons. Imports equal 6.0 billion gallons, which is the difference between U.S. consumption and U.S. production. Consumer surplus equals the sum of areas A, B, C, and D. Producer surplus equals the area E.

higher price, U.S. ethanol producers increase the quantity they supply from 3.0 billion gallons to 4.5 billion gallons. U.S. consumers, though, cut back their purchases of ethanol from 9.0 billion gallons to 7.5 billion gallons. Imports decline from 6.0 billion gallons (9.0 billion – 3.0 billion) to 3.0 billion gallons (7.5 billion – 4.5 billion). Equilibrium moves from point G to point H.

MyEconLab Animation

Figure 9.6

The Effects of a Tariff on Ethanol

Without a tariff on ethanol, U.S. producers will sell 3.0 billion gallons of ethanol, U.S. consumers will purchase 9.0 billion gallons, and imports will be 6.0 billion gallons. The U.S. price will equal the world price of \$1.00 per gallon. The \$0.50-per-gallon tariff raises the price of ethanol in the United States to \$1.50 per gallon, and U.S. producers increase the quantity they supply to 4.5 billion gallons. U.S. consumers reduce their purchases to 7.5 billion gallons. Equilibrium moves from point G to point H. The ethanol tariff causes a loss of consumer surplus equal to the area A + C + T + D. The area A is the increase in producer surplus due to the higher price. The area T is the government's tariff revenue. The areas C and D represent deadweight loss.

Loss of Consumer Surplus	=	Increase in Producer Surplus	+	Government Tariff Revenue	+	Deadweight Loss
A + C + T + D		A		T		C + D

By raising the price of ethanol from \$1.00 to \$1.50, the tariff reduces consumer surplus by the sum of areas A, T, C, and D. Area A is the increase in producer surplus from the higher price. The government collects tariff revenue equal to the tariff of \$0.50 per gallon multiplied by the 3.0 billion gallons imported. Area T represents the government's tariff revenue. Areas C and D represent losses to U.S. consumers that are not captured by anyone. These areas are deadweight loss and represent the decline in economic efficiency resulting from the ethanol tariff. Area C shows the effect of U.S. consumers being forced to buy from U.S. producers that are less efficient than foreign producers, and area D shows the effect of U.S. consumers buying less ethanol than they would have at the world price. As a result of the tariff, economic surplus has been reduced by the sum of areas C and D.

We can conclude that the tariff succeeds in helping U.S. ethanol producers but hurts U.S. consumers and the efficiency of the U.S. economy. MyEconLab Concept Check

Quotas and Voluntary Export Restraints

A **quota** is a numerical limit on the quantity of a good that can be imported, and it has an effect similar to that of a tariff. A quota is imposed by the government of the importing country. A **voluntary export restraint (VER)** is an agreement negotiated between two countries that places a numerical limit on the quantity of a good that can be imported by one country from the other country. In the 1980s, the United States and Japan negotiated a VER that limited the quantity of automobiles the United States would import from Japan. The Japanese government agreed to the VER primarily because it was afraid that if it did not, the United States would impose a tariff or quota on imports of Japanese automobiles. Quotas and VERs have similar economic effects.

The main purpose of most tariffs and quotas is to reduce the foreign competition that domestic firms face. For many years, Congress has imposed a quota on sugar imports to protect U.S. sugar producers. Figure 9.7 shows the actual statistics for the

Quota A numerical limit a government imposes on the quantity of a good that can be imported into the country.

Figure 9.7

The Economic Effect of the U.S. Sugar Quota

Without a sugar quota, U.S. sugar producers would have sold 9.2 billion pounds of sugar, U.S. consumers would have purchased 26.1 billion pounds of sugar, and imports would have been 16.9 billion pounds. The U.S. price would have equaled the world price of \$0.20 per pound. Because the sugar quota limits imports to 6.9 billion pounds (the bracket in the graph), the price of sugar in the United States rises to \$0.33 per pound, and U.S. producers supply 17.1 billion pounds. U.S. consumers purchase 24.0 billion pounds rather than the 26.1 billion pounds they would purchase at the world price. Without the import quota, equilibrium would be at point E; with the quota, equilibrium is at point F. The sugar quota causes a loss of consumer surplus equal to the area A + B + C + D. The area A is the gain to U.S. sugar producers. The area B is the gain to foreign sugar producers. The areas C and D represent deadweight loss. The total loss to U.S. consumers in 2014 was \$3.26 billion.

U.S. sugar market in 2014. The effect of a quota is very similar to the effect of a tariff. By limiting imports, a quota forces the domestic price of a good above the world price. In this case, the sugar quota limits sugar imports to 6.9 billion pounds per year (shown by the bracket in Figure 9.7), forcing the U.S. price of sugar up to \$0.33 per pound, or \$0.13 higher than the world price of \$0.20 per pound. The U.S. price is above the world price because the quota keeps foreign sugar producers from selling the additional sugar in the United States that would drive the U.S. price down to the world price. At a price of \$0.33 per pound, U.S. producers increase the quantity of sugar they supply from the 9.2 billion pounds they would supply at the world price to 17.1 billion pounds, and U.S. consumers cut back their purchases of sugar from the 26.1 billion pounds they would purchase at the world price to the 24.0 billion pounds they are willing to purchase at the higher U.S. price. If there were no import quota, equilibrium would be at the world price (point E), but with the quota, equilibrium is at the U.S. price (point F).

MyEconLab Concept Check

Measuring the Economic Effect of the Sugar Quota

We can use the concepts of consumer surplus, producer surplus, and deadweight loss to measure the economic impact of the sugar quota. Without a sugar quota, the world price of \$0.20 per pound would also be the U.S. price. In Figure 9.7, without a sugar quota, consumer surplus would equal the area above the \$0.20 price line and below the demand curve. The sugar quota causes the U.S. price to rise to \$0.33 and reduces consumer surplus by the area $A + B + C + D$. Without a sugar quota, producer surplus received by U.S. sugar producers would be equal to the area below the \$0.20 price line and above the supply curve. The higher U.S. price resulting from the sugar quota increases the producer surplus of U.S. sugar producers by an amount equal to area A.

A foreign producer must have a license from the U.S. government to import sugar under the quota system. Therefore, a foreign sugar producer that is lucky enough to have an import license also benefits from the quota because it is able to sell sugar in the U.S. market at \$0.33 per pound instead of \$0.20 per pound. Area B is the gain to foreign sugar producers. Areas A and B represent transfers from U.S. consumers of sugar to U.S. and foreign producers of sugar. Areas C and D represent losses to U.S. consumers that are not captured by anyone. These areas are deadweight loss and represent the decline in economic efficiency resulting from the sugar quota. Area C shows the effect of U.S. consumers being forced to buy from U.S. producers that are less efficient than foreign producers, and area D shows the effect of U.S. consumers buying less sugar than they would have at the world price.

Figure 9.7 provides enough information to calculate the dollar value of each of the four areas. The table in the figure shows the results of these calculations. The total loss to consumers from the sugar quota was \$3.26 billion in 2014. About 52 percent of the loss to consumers, or \$1.71 billion, was gained by U.S. sugar producers as increased producer surplus. About 28 percent, or \$0.90 billion, was gained by foreign sugar producers as increased producer surplus, and about 20 percent, or \$0.65 billion, was a deadweight loss to the U.S. economy. The U.S. International Trade Commission estimates that eliminating the sugar quota would result in the loss of about 3,000 jobs in the U.S. sugar industry. The cost to U.S. consumers of saving these jobs is equal to \$3.26 billion/3,000, or about \$1.1 million per job each year. In fact, this cost is an underestimate because eliminating the sugar quota would result in new jobs being created, particularly in the candy industry. Over the years, several U.S. candy companies—including the makers of Life Savers and Star Brite mints—have moved factories to other countries to escape the effects of the sugar quota. Partly as a result of the sugar quota, total employment in U.S. chocolate and candy firms that use sugar as an input declined by one-third between 1996 and 2014.

Measuring the Economic Effect of a Quota

Suppose that the United States currently both produces and imports apples. The U.S. government then decides to restrict international trade in apples by imposing a quota that allows imports of only 4 million boxes of apples into the United States each year. The figure shows the results of imposing the quota.

Fill in the following table, using the prices, quantities, and letters in the figure:

	Without Quota	With Quota
World price of apples		
U.S. price of apples		
Quantity supplied by U.S. firms		
Quantity demanded by U.S. consumers		
Quantity imported		
Area of consumer surplus		
Area of domestic producer surplus		
Area of deadweight loss		

Solving the Problem

Step 1: Review the chapter material. This problem is about measuring the economic effects of a quota, so you may want to review the sections “Quotas and Voluntary Export Restraints,” which begins on page 357, and “Measuring the Economic Effect of the Sugar Quota,” which begins on page 358.

Step 2: Fill in the table. After studying Figure 9.7, you should be able to fill in the table. Remember that consumer surplus is the area below the demand curve and above the market price.

	Without Quota	With Quota
World price of apples	\$10	\$10
U.S. price of apples	\$10	\$12
Quantity supplied by U.S. firms	6 million boxes	10 million boxes
Quantity demanded by U.S. consumers	16 million boxes	14 million boxes
Quantity imported	10 million boxes	4 million boxes
Area of consumer surplus	$A + B + C + D + E + F$	$A + B$
Area of domestic producer surplus	G	$G + C$
Area of deadweight loss	No deadweight loss	$D + F$

The High Cost of Preserving Jobs with Tariffs and Quotas

The sugar quota is not the only government policy that imposes a high cost on U.S. consumers to save jobs at U.S. firms. Table 9.5 shows the costs tariffs and quotas impose on U.S. consumers per year for each job saved in several industries. Note that the tariff on shoes discussed in the chapter opener costs U.S. consumers \$300,000 per year for each job saved for just the two types of shoes listed.

Just as the sugar quota costs jobs in the candy industry, other tariffs and quotas cost jobs outside the industries immediately affected. For example, in 1991, the United States imposed tariffs on flat-panel displays used in laptop computers. The tariff was good news for U.S. producers of these displays but bad news for companies producing laptop computers. Toshiba, Sharp, and Apple all closed their U.S. laptop production facilities and moved production overseas. In fact, whenever one industry receives tariff or quota protection, other domestic industries lose jobs. MyEconLab Concept Check

Smoot-Hawley, the Politics of Tariffs, and the Cost of Protecting a Vanishing Industry

In the 1920s, U.S. farmers faced severe financial hardship. Congress and the president responded to that hardship. As a result of that response, in 2015 many U.S. businesses that import foreign-made shoes into the United States paid tariffs of 35 percent or more on the value of the shoes. Sound illogical? The politics of tariffs can certainly seem to be.

Here is the connection between farmers in the 1920s and shoes today: The 1920s were a period of rapid economic progress in the United States, with the mass production of automobiles, the expansion of electricity use in homes and businesses, improvements in public health, a boom in housing construction, and the development of network radio and talking films. But the incomes of many farmers declined, partly because of increasing agricultural production from foreign competitors. During the 1928 presidential election, Herbert Hoover, the Republican Party candidate, promised that if elected, he would aid farmers by raising tariffs on agriculture goods imported into the United States.

After Hoover won the election, Congress in 1929 considered a new tariff bill. During Congressional negotiations, the number of products on which tariffs would be raised quickly expanded beyond agricultural products, in a process known as *logrolling*.

How does the Smoot-Hawley Tariff Act of 1930 affect what you pay for your shoes today?

Logrolling refers to members of Congress promising to support each other's legislation. In this case, a member of Congress from a district with a lot of dairy farms who wanted the tariff on milk increased would seek out a member of Congress from a district with shoe factories and negotiate along these lines: "If you vote to increase tariffs on milk, I'll vote to increase tariffs on shoes." The law Congress finally passed in 1930 is called the *Smoot-Hawley Tariff Act* and raised tariffs to the highest level in U.S. history. As a percentage of the value of imports covered by the law, tariffs reached nearly 60 percent.

The process of logrolling can lead to very detailed and complex tariffs as members of Congress attempt to protect specific firms in their districts from competition from foreign producers. For example, the 2015 tariff on shoes contains hundreds of entries, many aimed at very specific types of shoes. Here are *just a few* of those entries:

Type of Shoe	Tariff
Footwear designed to be worn over, or in lieu of, other footwear as a protection against water, oil, grease, or chemicals or cold or inclement weather	37.5%
Parts of footwear (including uppers whether or not attached to soles other than outer soles); removable insoles, heel cushions and similar articles; gaiters, leggings and similar articles, and parts thereof: Valued not over \$3/pair	33.6%
Parts of footwear (including uppers whether or not attached to soles other than outer soles); removable insoles, heel cushions and similar articles; gaiters, leggings and similar articles, and parts thereof: Valued over \$3/pair but not over \$6.50	63 cents per pair plus 26.2%
Tennis shoes, basketball shoes, gym shoes, training shoes and the like, costing more than \$12 per pair	20.0%
Footwear having uppers of which over 90 percent of the external surface area (including any accessories or reinforcements such as those mentioned in note 4(a) to this chapter) is rubber or plastics (except footwear having a foxing or a foxing-like band applied or made on a base or platform of cork)	12.5%
Footwear with open toes or open heels; footwear of the slip-on type, that is held to the foot without the use of laces or buckles or other fasteners, the foregoing except footwear of subheading 6402.99.20 and except footwear having a foxing or a foxing-like band applied or made on a base or platform of cork	12.5%
House slippers valued not over \$3 per pair having outer soles with textile materials having the greatest surface area in contact with the ground, but not taken into account under the terms of additional U.S. note 5 to this chapter	12.5%
Footwear having uppers of which over 90 percent of the external surface area (including any accessories or reinforcements such as those mentioned in note 4(a) to this chapter) is rubber or plastics (except footwear having a foxing or a foxing-like band applied or made on a base or platform of wood)	8.0%
Footwear with outer soles of rubber, plastics, leather or composition leather and uppers of textile materials: Having soles (or mid-soles, if any) of rubber or plastics which are affixed to the upper exclusively with an adhesive (any mid-soles also being affixed exclusively to one another and to the sole with an adhesive); the foregoing except footwear having uppers of vegetable fibers and having outer soles with textile materials having the greatest surface area in contact with the ground, but not taken into account under the terms of additional U.S. note 5 to this chapter	7.5%
Sandals and similar footwear of plastics, produced in one piece by molding	3.0%

Are you having trouble understanding the entries in the table? Imagine being the owner of a small business in 2015 who wants to import shoes. You will have a lot of difficulty just determining what tariff to pay, given the complexity of the law.

Canada, the largest trading partner of the United States, reacted to passage of the Smoot-Hawley Tariff by enacting large increases in tariffs on U.S. imports. Other countries raised tariffs as well, resulting in a *trade war* that led to a sharp decrease in global trade and helped increase the severity of the Great Depression of the 1930s.

Since the end of World War II in 1945, the United States and most other countries have engaged in rounds of negotiations that have greatly reduced tariffs on most goods. But the United States continues to impose high tariffs on shoes 85 years after the passage of Smoot-Hawley. During that time, employment in the U.S. shoe industry has fallen from 275,000 workers to fewer than 15,000, as more than 98 percent of the shoes sold in the United States are imported. As Table 9.5 on page 360 shows, the cost to U.S. consumers of preserving those remaining jobs is very high. The total cost to U.S. consumers from higher shoe prices due to the tariff is more than \$2 billion per year. The fact that high tariffs on shoes have survived despite few shoes being manufactured in the United States anymore demonstrates how difficult it can sometimes be to remove government protection for an industry once the protection has been enacted.

One way to avoid logrolling when passing tariff laws is for Congress to give the president *fast-track authority* when negotiating trade agreements with other countries. Under fast-track authority, once the president has finished negotiating an agreement with other countries, Congress can either pass or reject the agreement but cannot change any of its provisions. With fast-track authority, the vote trading that occurred during the Congressional deliberations over Smoot-Hawley would not be possible. In 2015, only after a long political struggle was President Obama able to get Congress to grant him the fast-track authority he needed to finish negotiating the Trans-Pacific Partnership trade agreement.

Gains from Unilateral Elimination of Tariffs and Quotas

Some politicians argue that eliminating U.S. tariffs and quotas would help the U.S. economy only if other countries eliminated their tariffs and quotas in exchange. It is easier to gain political support for reducing or eliminating tariffs or quotas if it is done as part of an agreement with other countries that involves their eliminating some of their tariffs or quotas. But as the example of the sugar quota shows, *the U.S. economy would experience a gain in economic surplus from the elimination of tariffs and quotas even if other countries did not reduce their tariffs and quotas.*

MyEconLab Concept Check

Other Barriers to Trade

In addition to tariffs and quotas, governments sometimes erect other barriers to trade. For example, all governments require that imports meet certain health and safety requirements. Sometimes, however, governments use these requirements to shield domestic firms from foreign competition. For example, a government may impose stricter health and safety requirements on imported goods than on goods produced by domestic firms.

Many governments also restrict imports of certain products on national security grounds. The argument is that in time of war, a country should not be dependent on imports of critical war materials. Once again, these restrictions are sometimes used more to protect domestic companies from competition than to protect national security. For example, for years, the U.S. government would buy military uniforms only

from U.S. manufacturers, even though uniforms are not a critical war material. The Defense Department gives each army recruit a voucher to purchase a pair of athletic shoes for training. New Balance has attempted to force the Defense Department to require the vouchers be used only to purchase U.S.-made shoes. Many officials in the Defense Department didn't see soldiers training in foreign-made running shoes as a threat to national security.

9.5 The Arguments over Trade Policies and Globalization

LEARNING OBJECTIVE: Evaluate the arguments over trade policies and globalization.

The argument over whether the U.S. government should regulate international trade has continued since the founding of the country. One particularly controversial attempt to restrict trade took place during the Great Depression of the 1930s. At that time, the United States and other countries attempted to help domestic firms by raising tariffs on imports. The United States started the process by passing the Smoot-Hawley Tariff in 1930, which raised average tariff rates to nearly 60 percent. As other countries retaliated by raising their tariffs, international trade collapsed.

By the end of World War II in 1945, government officials in the United States and Europe were looking for a way to reduce tariffs and revive international trade. To help achieve this goal, they set up the General Agreement on Tariffs and Trade (GATT) in 1948. Countries that joined the GATT agreed not to impose new tariffs or import quotas. In addition, a series of *multilateral negotiations*, called *trade rounds*, took place, in which countries agreed to reduce tariffs from the very high levels of the 1930s.

In the 1940s, most international trade was in goods, and the GATT agreement covered only goods. In the following decades, trade in services and products incorporating *intellectual property*, such as software programs and movies, grew in importance. Many GATT members pressed for a new agreement that would cover services and intellectual property, as well as goods. A new agreement was negotiated, and in January 1995, the GATT was replaced by the **World Trade Organization (WTO)**, headquartered in Geneva, Switzerland. More than 150 countries are currently members of the WTO.

World Trade Organization (WTO) An international organization that oversees international trade agreements.

Why Do Some People Oppose the World Trade Organization?

During the years immediately after World War II, many low-income, or developing, countries enacted high tariffs and restricted investment by foreign companies. When these policies failed to produce much economic growth, many of these countries decided during the 1980s to become more open to foreign trade and investment. This process became known as **globalization**. Most developing countries joined the WTO and began to follow its policies.

Globalization The process of countries becoming more open to foreign trade and investment.

During the 1990s, opposition to globalization began to increase. Over the years, protests, which have sometimes turned violent, have occurred in cities hosting WTO meetings. Why would attempts to reduce trade barriers with the objective of increasing income around the world cause such a furious reaction? The opposition to the WTO comes from three sources. First, some opponents are specifically against the globalization process that began in the 1980s and became widespread in the 1990s. Second, other opponents have the same motivation as the supporters of tariffs in the 1930s—to erect trade barriers to protect domestic firms from foreign competition. Third, some critics of the WTO support globalization in principle but believe that the WTO favors the interests of the high-income countries at the expense of the low-income countries. Let's look more closely at the sources of opposition to the WTO.

Anti-Globalization Many of those who protest at WTO meetings distrust globalization. Some believe that free trade and foreign investment destroy the distinctive cultures of many countries. As developing countries began to open their economies to imports from the United States and other high-income countries, the imports of food,

clothing, movies, and other goods began to replace the equivalent local products. So, a teenager in Thailand might be sitting in a McDonald's restaurant, wearing Levi's jeans and a Ralph Lauren shirt, listening to a song by Lady Gaga on his iPhone, before downloading *Star Wars: The Force Awakens* to his iPad. Globalization has increased the variety of products available to consumers in developing countries, but some people argue that this is too high a price to pay for what they see as damage to local cultures.

Globalization has also allowed multinational corporations to relocate factories from high-income countries to low-income countries. These new factories in Indonesia, Malaysia, Pakistan, and other countries pay much lower wages than are paid in the United States, Europe, and Japan and often do not meet the environmental or safety regulations that are imposed in high-income countries. Some factories use child labor, which is illegal in high-income countries. Some people have argued that firms with factories in developing countries should pay workers wages as high as those paid in high-income countries. They also believe these firms should abide by the health, safety, and environmental regulations that exist in the high-income countries.

The governments of most developing countries have resisted these proposals. They argue that when the currently rich countries were poor, they also lacked environmental or safety standards, and their workers were paid low wages. They argue that it is easier for rich countries to afford high wages and environmental and safety regulations than it is for poor countries. They also point out that many jobs that seem to have very low wages based on the standards of high-income countries are often better than the alternatives available to workers in low-income countries.

“Old-Fashioned” Protectionism The anti-globalization argument against free trade and the WTO is relatively new. Another argument against free trade, called *protectionism*, has been around for centuries. **Protectionism** is the use of trade barriers to shield domestic firms from foreign competition. For as long as international trade has existed, governments have attempted to restrict it to protect domestic firms. As we saw with the analysis of the sugar quota, protectionism causes losses to consumers and eliminates jobs in the domestic industries that buy the protected product. In addition, by reducing the ability of countries to produce according to comparative advantage, protectionism reduces incomes.

Why, then, does protectionism attract support? Protectionism is usually justified on the basis of one of the following arguments:

- **Saving jobs.** Supporters of protectionism argue that free trade reduces employment by driving domestic firms out of business. It is true that when more-efficient foreign firms drive less-efficient domestic firms out of business, jobs are lost, but jobs are also lost when more-efficient domestic firms drive less-efficient domestic firms out of business. These job losses are rarely permanent. In the U.S. economy, jobs are lost and new jobs are created continually. No economic study has ever found a long-term connection between the total number of jobs available and the level of tariff protection for domestic industries. In addition, trade restrictions destroy jobs in some industries at the same time that they preserve jobs in others. The U.S. sugar quota may have saved jobs in the U.S. sugar industry, but it has also destroyed jobs in the U.S. candy industry.
- **Protecting high wages.** Some people worry that firms in high-income countries will have to start paying much lower wages to compete with firms in developing countries. This fear is misplaced, however, because free trade actually raises living standards by increasing economic efficiency. When a country practices protectionism and produces goods and services it could obtain more inexpensively from other countries, it reduces its standard of living. The United States could ban imports of coffee and begin growing it domestically. But doing so would entail a very high opportunity cost because coffee could only be grown in the continental United States in greenhouses and would require large amounts of labor and equipment. The coffee would have to sell for a very high price to cover these costs. Suppose the United States did ban coffee imports: Eliminating the ban at some

Protectionism The use of trade barriers to shield domestic firms from foreign competition.

future time would eliminate the jobs of U.S. coffee workers, but the standard of living in the United States would rise as coffee prices declined and labor, machinery, and other resources were moved out of coffee production and into production of goods and services for which the United States has a comparative advantage.

- **Protecting infant industries.** It is possible that firms in a country may have a comparative advantage in producing a good, but because the country begins production of the good later than other countries, its firms initially have higher costs. In producing some goods and services, substantial “learning by doing” occurs. As workers and firms produce more of the good or service, they gain experience and become more productive. Over time, these firms will have lower costs and can charge lower prices. As the firms in the “infant industry” gain experience, they will be able to compete successfully with foreign producers. Under free trade, however, they may not get a chance. The established foreign producers can sell the product at a lower price and drive domestic producers out of business before they gain enough experience to compete. To economists, the infant industry argument is the most persuasive of the protectionist arguments. It has a significant drawback, however. Tariffs eliminate the need for firms in an infant industry to become productive enough to compete with foreign firms. After World War II, the governments of many developing countries used the infant industry argument to justify high tariff rates. Unfortunately, most of their infant industries never grew up, and they continued for years as inefficient drains on their economies.
- **Protecting national security.** A country will typically not want to rely on other countries for goods that are critical to its military defense. For example, the United States would probably not want to import all its jet fighter engines from China. The definition of which goods are critical to military defense is a slippery one, however. In fact, it is rare for an industry to ask for protection without raising the issue of national security, even if its products have mainly nonmilitary uses.

Protecting Consumer Health or Protecting U.S. Firms from Competition?

The World Trade Organization and other international agreements limit the use of tariffs and quotas. So to protect firms from foreign competition, governments

sometimes regulate imports by claiming that they pose a threat to consumer health or safety.

Is imported catfish safe for U.S. consumers to eat, or does it contain bacteria and dangerous chemicals? The U.S. states that produce the most catfish are Alabama, Arkansas, Mississippi, and Texas. In 2008, members of Congress from those states pushed through legislation setting up a catfish inspection office in the U.S. Department of Agriculture. By 2014, the office had spent \$20 million but had not actually inspected any imported catfish. The money had been spent on just setting up offices and paying administrators’ salaries. That year, Congress set a deadline for the inspection program to begin.

Vietnam and other countries that export catfish to the United States objected that the real purpose of the inspections was to erect a barrier to trade. Those governments argued that the inspections would violate the commitments of the United States under the World Trade Organization not to erect barriers to trade. Further complicating the situation for the U.S. government was the fact that these countries were in talks with the United States about the Trans-Pacific Partnership, an agreement to reduce trade barriers among countries in the Pacific that we discussed earlier in this chapter. A trade war over catfish could interfere with completing those talks.

A study by the U.S. Government Accountability Office indicated that the health risk to U.S. consumers from imported catfish was very low, even without the proposed inspections. Some members of Congress from states that do not produce catfish also

Are restrictions on catfish imports protecting the health of U.S. consumers or the interests of U.S. producers?

argued that new inspections of imported catfish were unnecessary and would result in U.S. consumers paying higher prices.

Congress and the president are often caught in a policy dilemma over imports. Firms want to reduce or eliminate sales lost to imports, but imposing trade barriers reduces economic efficiency, lowers incomes, and invites retaliation from foreign governments. Although some imported goods can, in fact, pose threats to the health and safety of U.S. consumers, some health and safety regulations are intended to protect the U.S. firms involved rather than U.S. consumers.

Dumping Selling a product for a price below its cost of production.

Dumping

In recent years, the United States has extended protection to some domestic industries by using a provision in the WTO agreement that allows governments to impose tariffs in the case of *dumping*. **Dumping** is selling a product for a price below its cost of production. Using tariffs to offset the effects of dumping is controversial despite being allowed under the WTO agreement.

In practice, it is difficult to determine whether foreign companies are dumping goods because the true production costs of a good are not easy for governments to calculate. As a result, the WTO allows countries to determine that dumping has occurred if a product is exported for a lower price than it sells for on the home market. There is a problem with this approach, however. Often there are good business reasons for a firm to sell a product for different prices to different consumers. For example, the airlines charge business travelers higher ticket prices than leisure travelers. Firms also use “loss leaders”—products that are sold below cost, or even given away free—when introducing a new product or, in the case of retailing, to attract customers who will also buy full-price products. For example, during the holiday season, Walmart sometimes offers toys at prices below what it pays to buy them from manufacturers. It’s unclear why these normal business practices should be unacceptable when used in international trade.

Positive versus Normative Analysis (Once Again)

Economists emphasize the burden on the economy imposed by tariffs, quotas, and other government restrictions on free trade. Does it follow that these interferences are bad? Remember that positive analysis concerns what *is*, while normative analysis concerns what *ought to be*. Measuring the effect of the sugar quota on the U.S. economy is an example of positive analysis. Asserting that the sugar quota is bad public policy and should be eliminated is normative analysis. The sugar quota—like all other interferences with trade—makes some people better off and some people worse off, and it reduces total income and consumption. Whether increasing the profits of U.S. sugar companies and the number of workers they employ justifies the costs imposed on consumers and the reduction in economic efficiency is a normative question.

Most economists do not support interferences with trade, such as the sugar quota. Few people become economists if they don’t believe that markets should be as free as possible. But the opposite view is certainly intellectually respectable. It is possible for someone to understand the costs of tariffs and quotas but still believe that tariffs and quotas are a good idea, perhaps because he or she believes unrestricted free trade would cause too much disruption to the economy.

The success of industries in getting the government to erect barriers to foreign competition depends partly on some members of the public knowing the costs of trade barriers but supporting them anyway. However, two other factors are also at work:

1. The costs tariffs and quotas impose on consumers are large in total but relatively small per person. For example, the sugar quota imposes a total burden of \$3.26 billion per year on consumers. Spread across 320 million Americans, the burden is only about \$10 per person—too little for most people to worry about, even if they know the burden exists.
2. The jobs lost to foreign competition are easy to identify, but the jobs created by foreign trade are less easy to identify.

In other words, the industries that benefit from tariffs and quotas benefit a lot—for example, the sugar quota increases the profits of U.S. sugar producers by \$1.71 billion per year—while each consumer loses relatively little. This concentration of benefits and widely spread burdens makes it easy to understand why members of Congress receive strong pressure from some industries to enact tariffs and quotas and relatively little pressure from the general public to reduce them.

Economics in Your Life

Did You Know There Is a Tariff on Running Shoes?

At the beginning of the chapter, we asked you to consider why the federal government has imposed a tariff on shoes, even though there are very few shoe factories remaining in the United States. We also asked why relatively few people have heard of this tariff. In the chapter, we saw that trade restrictions tend to preserve relatively few jobs in the protected industries, while they lead to job losses in other industries and cost consumers billions of dollars per year in higher prices. However, we have also seen that *per person*, the burden of specific trade restrictions can be small. For example, the tariff on shoes might cause you to pay \$20 dollars more for a \$100 pair of running shoes. The average person buys only one pair of running shoes per year, and few people will take the trouble of writing a letter to their member of Congress or otherwise express their views to try to save \$20 per year. In fact, few people will even spend the time to become aware that a specific trade restriction exists. So, if you had never heard of the shoe tariff before you read this chapter, you are certainly not alone.

Conclusion

There are few issues economists agree upon more than the economic benefits of free trade. However, there are few political issues as controversial as government policy toward trade. Many people who would be reluctant to see the government interfere with domestic trade are quite willing to see it interfere with international trade. The damage high tariffs inflicted on the world economy during the 1930s shows what can happen when governments around the world abandon free trade. Whether future episodes of that type can be avoided is by no means certain.

The United States in the International Economy, pages 344–347

LEARNING OBJECTIVE: Discuss the role of international trade in the U.S. economy.

Summary

International trade has been increasing in recent decades, in part because of reductions in *tariffs* and other barriers to trade. A **tariff** is a tax imposed by a government on imports. The quantity of goods and services the United States imports and exports has been continually increasing. **Imports** are goods and services bought domestically but produced in other countries. **Exports** are goods and services produced domestically and sold to other countries. Today, the United States is the second-leading exporting country in the world behind China, and about 20 percent of U.S. manufacturing jobs depend on exports.

Review Questions

- 1.1 Briefly explain whether the value of U.S. exports is typically larger or smaller than the value of U.S. imports.
- 1.2 Define informative content of a time series illustrating imports and exports divided by GDP of a country over 50 years.
- 1.3 Briefly explain whether you agree with the following statement: “International trade is more important to the U.S. economy than it is to most other economies.”

9.2

Comparative Advantage in International Trade, pages 347–349

LEARNING OBJECTIVE: Explain the difference between comparative advantage and absolute advantage in international trade.

Summary

Comparative advantage is the ability of an individual, a firm, or a country to produce a good or service at the lowest **opportunity cost**. **Absolute advantage** is the ability to produce more of a good or service than competitors when using the same amount of resources. Countries trade on the basis of comparative advantage, not on the basis of absolute advantage.

Problems and Applications

- 1.4 Do you think that all firms, in every sector, are equally affected by the degree of openness of an economy? Briefly explain your answer with examples.
- 1.5 Briefly explain whether you agree with the following statement: “Japan has always been much more heavily involved in international trade than are most other nations. In fact, today Japan exports a larger fraction of its GDP than Germany, Great Britain, or the United States.”
- 1.6 Why might a smaller country, such as the Netherlands, be more likely to import and export larger fractions of its GDP than would a larger country, such as China or the United States?
- 1.7 (Related to the Chapter Opener on page 343 and the Making the Connection on page 345) New Balance manufactures shoes in the United States, so you might expect that the firm would benefit from a tariff on shoes. Yet New Balance did not actively oppose the Obama administration’s attempts to eliminate the shoe tariff imposed on countries that would be part of the Trans-Pacific Partnership. Briefly explain New Balance’s position.

Review Questions

- 2.1 Are absolute advantage and comparative advantage static concepts? Does the answer depend on the goods and services being considered?
- 2.2 A World Trade Organization (WTO) publication calls comparative advantage “arguably the single most powerful insight in economics.” What is comparative advantage? What makes it such a powerful insight?

Problems and Applications

- 2.3 In the 2012 Summer Olympic Games, Ashton Eaton (from the United States) won a gold medal in the decathlon, which requires athletes to compete in 10 different track and field events. In one of these events Eaton ran a 100-meter race in 10.35 seconds. In a separate event, Usain Bolt (from Jamaica) won a gold medal and set a world record by running 100 meters in 9.58 seconds.
- Which performance—Eaton’s or Bolt’s—is better explained by the concept of comparative advantage? Briefly explain.
 - Based on their performance at the 2012 Olympic Games, can we say whether Eaton or Bolt was the better athlete? Briefly explain.
- 2.4 An article in the *New York Times* quoted an economist as arguing that “global free trade and the European single market ... encourage countries to specialize in sectors where they enjoy comparative advantage. Germany’s [comparative advantage] is in cars and machine tools.” For the author’s observation to be correct, must Germany be able to produce more cars and machine tools per hour worked than do France, Italy, the United Kingdom, and Germany’s other trading partners? Briefly explain.

- 2.6 The following table shows the hourly output per worker for Greece and Italy measured as quarts of olive oil and pounds of pasta.

	Output per Hour of Work	
	Olive Oil	Pasta
Greece	4	2
Italy	4	8

Calculate the opportunity cost of producing olive oil and pasta in both Greece and Italy.

- 2.7 Using the numbers in the table, explain which country has a comparative advantage in producing smartwatches.

	Output per Hour of Work	
	Smartwatches	Fitness Bracelets
Switzerland	8	10
Canada	5	3

- 2.8 Consider Figure 9.3 on page 347 that depicts international trade as a percentage of GDP; would it be correct to conclude that Belgium is more open than the United States just because Belgian exports and imports relative to GDP are larger than exports and imports relative to GDP in the United States? Would the figure have been different had it contained the absolute values of exports and imports rather than the values relative to GDP?
- 2.9 While running for president, Barack Obama made the following statement: “Well, look, people don’t want a cheaper T-shirt if they’re losing a job in the process.” What did Obama mean by the phrase “losing a job in the process”? Using the economic concept of comparative advantage, explain under what circumstances it would make sense for the United States to produce all of the T-shirts purchased in the United States. Do you agree with President Obama’s statement? Briefly explain.

9.3

How Countries Gain from International Trade, pages 349–354

LEARNING OBJECTIVE: Explain how countries gain from international trade.

Summary

Autarky is a situation in which a country does not trade with other countries. The **terms of trade** is the ratio at which a country can trade its exports for imports from other countries. When a country specializes in producing goods for which it has a comparative advantage and trades for the other goods it needs, the country will have a higher level of income and consumption. We do not see complete specialization in production for three reasons: (1) Not all goods and services are traded internationally,

(2) production of most goods involves increasing opportunity costs, and (3) tastes for products differ across countries. Although the population of a country as a whole benefits from trade, firms—and their workers—that are unable to compete with lower-cost foreign producers lose. Among the main sources of comparative advantage are climate and natural resources, relative abundance of labor and capital, technology, and external economies. **External economies** are reductions in a firm’s costs that result from an increase in the size of an industry. A country

may develop a comparative advantage in the production of a good, and then as time passes and circumstances change, the country may lose its comparative advantage in producing that good and develop a comparative advantage in producing other goods.

Review Questions

- 3.1 Briefly explain how international trade increases a country's consumption.
- 3.2 What is meant by a country specializing in the production of a good? Is it typical for countries to be completely specialized? Briefly explain.
- 3.3 What are the main sources of comparative advantage?
- 3.4 If all countries gain from trade, why do most countries restrict trade in some way or another?

Problems and Applications

- 3.5 (Related to Solved Problem 9.3 on page 350) The following table shows the hourly output per worker in two industries in Chile and Argentina.

	Output per Hour of Work	
	Hats	Beer
Chile	8	6
Argentina	1	2

- a. Explain which country has an absolute advantage in the production of hats and which country has an absolute advantage in the production of beer.
- b. Explain which country has a comparative advantage in the production of hats and which country has a comparative advantage in the production of beer.
- c. Suppose that Chile and Argentina currently do not trade with each other. Each has 1,000 hours of labor to use producing hats and beer, and the countries are currently producing the amounts of each good shown in the following table.

	Hats	Beer
Chile	7,200	600
Argentina	600	800

Using this information, give a numerical example of how Chile and Argentina can both gain from trade. Assume that after trading begins, one hat can be exchanged for one barrel of beer.

- 3.6 (Related to Solved Problem 9.3 on page 350) A political commentator makes the following statement:

The idea that international trade should be based on the comparative advantage of each country is fine for rich countries like the United States and Japan. Rich countries have educated workers and large quantities of machinery and equipment. These advantages allow them to produce every product more efficiently than poor countries can. Poor countries like Kenya and Bolivia have nothing to gain from international trade based on comparative advantage.

Do you agree with this argument? Briefly explain.

- 3.7 Why is it unlikely for most countries to reach a state of complete specialization? Answer with reference to what was discussed in Chapter 2.
- 3.8 Define the 'terms of trade' and illustrate why it is a useful concept to use when studying international trade.
- 3.9 An article in the *New Yorker* states, "the main burden of trade-related job losses and wage declines has fallen on middle- and lower-income Americans. But ... the very people who suffer most from free trade are often, paradoxically, among its biggest beneficiaries." Explain how it is possible that middle- and lower-income Americans are both the biggest losers and at the same time the biggest winners from free trade.

- 3.10 Consider the sources of comparative advantage that you mentioned in your answer to Review Question 3.3. With reference to your answer, try to guess the comparative advantage sectors of the following countries.
 - a. Cape Verde, a low-income island country that is situated in the central Atlantic Ocean
 - b. Germany, a large industrialized economy located in continental Europe
 Briefly explain your guesses with the help of examples.
- 3.11 Suppose the graph on the next page shows Tanzania's production possibilities frontier for cashew nuts and mangoes. Assume that the output per hour of work is 8 bushels of cashew nuts or 2 bushels of mangoes and that Tanzania has 1,000 hours of labor. Without trade, Tanzania evenly splits its labor hours between cashews and mangoes and produces and consumes at point A.

- Suppose Tanzania opens trade with Kenya, and Kenya's output per hour of work is 1 bushel of cashew nuts or 1 bushel of mangoes. Having the comparative advantage, Tanzania completely specializes in cashew nuts. How many bushels of cashew nuts can Tanzania produce? Denote this point on the graph as point B.
- Suppose Tanzania keeps 5,000 bushels of cashew nuts and exports the remaining 3,000 bushels. If the terms of trade are 1 bushel of mangoes for 2 bushels of cashew nuts, how many bushels of mangoes will Tanzania get in exchange? Denote on the graph the quantity of cashew nuts and mangoes that Tanzania consumes

with trade and label this point as point C. How does point C with trade compare to point A without trade?

- With trade, is Tanzania producing on its production possibilities frontier? With trade, is Tanzania consuming on its production possibilities frontier?

Government Policies That Restrict International Trade, pages 354–363

LEARNING OBJECTIVE: Analyze the economic effects of government policies that restrict international trade.

Summary

Free trade is trade between countries without government restrictions. Government policies that interfere with trade usually take the form of *tariffs*, *quotas*, or *voluntary export restraints*. A **tariff** is a tax imposed by a government on imports. A **quota** is a numerical limit imposed by a government on the quantity of a good that can be imported into the country. A **voluntary export restraint (VER)** is an agreement negotiated between two countries that places a numerical limit on the quantity of a good that can be imported by one country from the other country. The federal government's sugar quota costs U.S. consumers \$3.26 billion per year, or about \$1.1 million per year for each job saved in the sugar industry. Saving jobs by using tariffs and quotas is often very expensive.

Review Questions

- What is a tariff? What is a quota? Give an example, other than a quota, of a nontariff barrier to trade.
- Who gains and who loses when a country imposes a tariff or a quota on imports of a good?

Problems and Applications

- Political commentator B. Bruce-Briggs once wrote the following in the *Wall Street Journal*: "This is not to say that the case for international free trade is invalid; it is just irrelevant. It is an 'if only everybody ... argument...'. In the real world almost everybody sees benefits in economic nationalism." What do you think he means by "economic nationalism"? Do you agree that a country benefits from free trade only if every other country also practices free trade? Briefly explain.

Source: B. Bruce-Briggs, "The Coming Overthrow of Free Trade," *Wall Street Journal*, February 24, 1983.

- Figure 9.6 on page 356 illustrates the effects of imposing a tariff on an imported good. This is usually done to discourage import of a product and protect domestic production of the same, and to give an impetus to domestic players in the sector. Imagine that you do not have access to such figures nor can you draw a diagram to figure out and analyze the effects of imposing a tariff on imports. In such a situation, how would you describe the effects of such a trade-restricting measure? Briefly explain.

- 4.5 Consider a country that imposes tariff on goods and services that are imported. In this context, answer the following.
- Does the tariff imposed lower the economic surplus of that country? Briefly explain your answer using a graph, showing the welfare effects of imposing the tariff on goods and services imported.
 - Does it affect the economic surplus of the other countries that are trading with the country that has imposed the tariff? If so, do you expect the economic surplus of those countries to increase or decrease?
 - Finally, briefly explain who benefits from the tariff in such a situation..

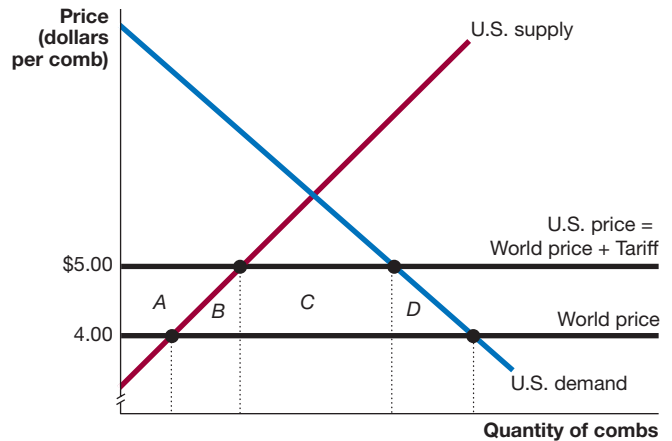

4.6 A notable example of a Voluntary Export Restraint (VER) is the following: in 1981, Japan agreed to limit its export of cars to the United States, imposing an annual limit of slightly less than 1.7 million units. The automobile industry in the United States achieved this result with a massive lobbying activity, which was the only subject benefiting from such a trade-restricting measure.

With reference to this example, explain the differences between a VER and a quota on imports.

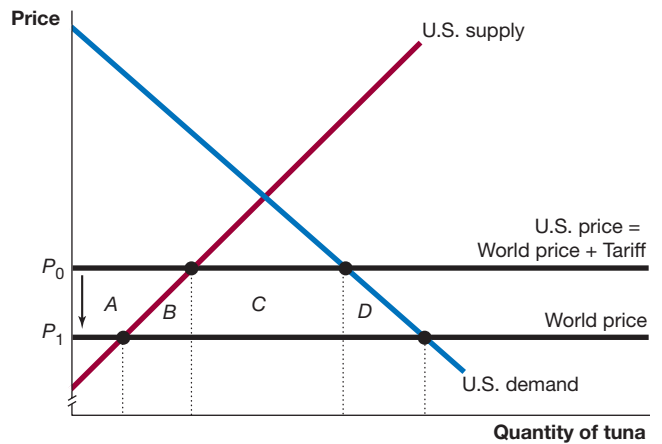

- 4.7 A student makes the following argument:
 Tariffs on imports of foreign goods into the United States will cause the foreign companies to add the amount of the tariff to the prices they charge in the United States for those goods. Instead of putting a tariff on imported goods, we should ban importing them. Banning imported goods is better than putting tariffs on them because U.S. producers benefit from the reduced competition, and U.S. consumers don't have to pay the higher prices caused by tariffs.

Briefly explain whether you agree with the student's reasoning.

- 4.8 Suppose China decides to pay large subsidies to any Chinese company that exports goods or services to the United States. As a result, these companies are able to sell products in the United States at far below their cost of production. In addition, China decides to bar all imports from the United States. The dollars that the United States pays to import Chinese goods are left in banks in China. Will this strategy raise or lower the standard of living in China? Will it raise or lower the standard of living in the United States? Briefly explain. Be sure to provide a definition of "standard of living" in your answer.
- 4.9 The following graph shows the effect on consumer surplus, producer surplus, government tariff revenue, and economic surplus of a tariff of \$1 per unit on imports of plastic combs into the United States. Use the areas denoted in the graph to answer the following questions.

- Which area shows the losses to U.S. consumers of buying a smaller quantity of combs than they would have if they could have purchased them at the world price?
 - Which area shows the losses to U.S. consumers of having to buy combs from U.S. producers who are less efficient than foreign producers?
 - Which areas show the deadweight loss to the U.S. economy as a result of the tariff on combs?
- 4.10 The following graph shows the situation after the U.S. government removes a tariff on imports of canned tuna.

- Which areas show the gain in consumer surplus?
 - Which area shows the loss in producer surplus?
 - Which area shows the loss in government tariff revenue?
 - Which areas show the gain in economic surplus?
- 4.11 According to an editorial in the *Washington Post*, "Sugar protectionism is a burden on consumers and a job-killer."
- In what sense does the United States practice "sugar protectionism"?
 - In what way is sugar protectionism a burden on consumers? In what way is it a job-killer?
 - If sugar protectionism has the bad effects stated in the editorial, why don't Congress and the president eliminate it?

4.12 (Related to Solved Problem 9.4 on page 359) Suppose that the United States currently both produces kumquats and imports them. The U.S. government then decides to restrict international trade in kumquats by imposing

a quota that allows imports of only 6 million pounds of kumquats into the United States each year. The figure shows the results of imposing the quota.

Fill in the table below using the letters in the figure:

	Without Quota	With Quota
World price of kumquats		
U.S. price of kumquats		
Quantity supplied by U.S. firms		
Quantity demanded		
Quantity imported		
Area of consumer surplus		
Area of domestic producer surplus		
Area of deadweight loss		

4.13 Suppose the government is considering imposing either a tariff or a quota on canned peaches. Assume that the proposed quota has the same effect on the U.S. price of canned peaches as the proposed tariff. Use the graph to answer the following questions.

- If the government imposes a tariff, which area shows the government tariff revenue?
- If the government imposes a quota, which area shows the gain to foreign producers of canned peaches?
- As a consumer of peaches, would you prefer the government impose the tariff or the quota? Briefly explain.

4.14 (Related to the Making the Connection on page 360) It is likely that most economists would agree with the following statement: trade barriers such as quotas and tariffs are an extremely costly way to preserve jobs. Why do you think it is impossible to prove such a statement using a graph such as Figure 9.6 that has been provided in this chapter? What is missing from this particular type of analysis (known as partial equilibrium analysis)? Briefly explain the reasons for your answer.

4.15 (Related to the Making the Connection on page 360) For several years, the United States imposed a tariff on tire imports. According to an analysis by economists Gary Clyde Hufbauer and Sean Lowry of the Peterson Institute, of the additional \$1.1 billion consumers spent on tires as a result of the tariff on Chinese tires, the workers whose jobs were saved in the U.S. tire industry received only about \$48 million in wages. Wouldn't it have been cheaper for the federal government to have raised taxes on U.S. consumers and given the money to tire workers rather than to have imposed a tariff? If so, why didn't the federal government adopt this alternative policy?

The Arguments over Trade Policies and Globalization, pages 363–367

LEARNING OBJECTIVE: Evaluate the arguments over trade policies and globalization.

Summary

The **World Trade Organization (WTO)** is an international organization that enforces trade agreements among members. The WTO has promoted **globalization**, the process of countries becoming more open to foreign trade and investment. Some critics

of the WTO argue that globalization has damaged local cultures around the world. Other critics oppose the WTO because they believe in **protectionism**, which is the use of trade barriers to shield domestic firms from foreign competition. The WTO allows countries to use tariffs in cases of **dumping**, when an imported product is sold for a price below its cost of production.

Economists can point out the burden imposed on the economy by tariffs, quotas, and other government interferences with free trade. But whether these policies should be used is a normative decision.

Problems and Applications

- 5.5 In 2015, several U.S. paper manufacturers asked the federal government to impose tariffs on paper imported from China, Indonesia, Brazil, Portugal, and Australia. According to an article in the *Wall Street Journal*, firms in these countries were accused of “dumping certain types of uncoated paper on the U.S. market, including that used for such things as computer printers, book publishing, junk mail and envelopes.” What is “dumping”? If the U.S. firms succeed in having tariffs imposed on imports of paper, briefly explain who will gain and who will lose.

- 5.6 The anti-globalization movement, also known as the counter-globalization movement, is critical of the globalization brought about by corporate capitalism. The movement got widespread mainstream media attention after protests against the WTO in Seattle, Washington, in late November and early December, 1999. Anti-globalization activists oppose large multi-national corporations having unregulated political power, and the powers exercised through trade agreements and deregulated financial markets.

According to them, the policies of corporate globalization have exacerbated global poverty and have also increased economic inequality. They hold protests outside meetings and conventions of international institutions, such as the WTO, the IMF, the World Bank, and the G8 (a forum of the governments of 8 of the world’s largest economies: Canada, Japan, Russia, the U.S., Germany, France, and Italy). The movement has its own annual gathering, known as the World Social Forum (the date deliberately coincides with the date for the annual World Economic Forum), and has launched campaigns that target multinational corporations such as Nike and Monsanto. This particular movement also advocates participatory democracy and seeks to increase popular control of political and economic life (according to a study by Engler, 2007).

Suppose you are to meet with one such activist from the anti-globalization movement. Briefly explain how you would present an argument in favor of free trade.

I just know that if I buy something produced in America, I create a job for an American, and if I buy something produced in Brazil, I create a job for a Brazilian.” Do you agree with this statement? When the United States imports products for which it does not have a comparative advantage, does that mean that there are fewer jobs in the United States? In the example with Japan and the United States producing and trading smartwatches and tablets, when the United States imports smartwatches from Japan, does the number of jobs in the United States decline?
- 5.8 Every year, the Gallup poll asks a sample of people in the United States whether they believe foreign trade provides “an opportunity for economic growth through increased U.S. exports,” or whether they believe foreign trade represents “a threat to the economy from foreign imports.” The table shows the responses for two years:

View of Foreign Trade			
Year	View of Foreign Trade		State of the U.S. Economy
	Favorable to Foreign Trade	Unfavorable	
2008	41%	52%	Deep economic recession
2015	58%	33%	Economic expansion

- a. Do you believe that foreign trade helps or hurts the economy? (Be sure to define what you mean by “helps” or “hurts.”)
- b. Why might the general public’s opinion of foreign trade be substantially different during an economic recession, when production and employment are falling, than during an economic expansion, when production and employment are increasing?
- c. Typically polls show that people in the United States under 30 years of age have a more favorable opinion of foreign trade than do people age 65 and over. Why might younger people have a more favorable view of foreign trade than older people?

J.C. Penney Customers Didn't Buy into "Everyday Low Prices"

In 2010, the J.C. Penney department store chain had nearly 600 "sales," and it sold almost three-quarters of its products at prices marked down by at least 50 percent. However, these sales were illusions because Penney had raised prices before discounting them. The company also often required customers to clip coupons to get the sale price. Soon after being named chief executive officer (CEO) of Penney in 2011, Ron Johnson, who had had a successful career as head of Apple's retail stores, decided to try a new pricing strategy of "everyday low prices" that eliminated most sales and coupons. But the new pricing policy backfired. Penney's sales plunged 25 percent in 2012, and the company fired Johnson after only 17 months. By 2015, Penney was still struggling, with its revenue and profits remaining well below 2010 levels.

What was wrong with Johnson's pricing policy? First, the everyday low prices ended up being higher than the sale prices under the previous pricing policy. Some customers noticed and switched to shopping at Walmart and other department stores. Some economists, though, believe that Johnson ran into an even bigger problem: Although economists generally assume that people have enough information to make optimal buying decisions, this assumption may not always be accurate. For example,

many consumers have only a rough idea of the typical price of a pair of jeans or a shirt. These consumers have difficulty knowing whether everyday low prices really are low. Instead, they wait for sales and use coupons because they believe doing so allows them to buy at lower-than-normal prices. As Alexander Chernev of Northwestern University put it, "J.C. Penney might say it's a fair price, but why should consumers trust J.C. Penney?" He argued that consumers "want a great deal," which they believe they get only if a store is having a sale or if they use coupons.

We can better understand the failure of Penney's pricing strategy by using insights from *behavioral economics*, which is the study of situations in which people make choices that do not appear to be economically rational. Firms must understand consumer behavior to determine what strategies are likely to be most effective in selling their products. In this chapter, we will examine how consumers make decisions about which products to buy.

Economics in Your Life

Do You Make Rational Decisions?

Economists generally assume that people make decisions in a rational, consistent way. But are people actually as rational as economists assume? Consider the following situation: You bought a concert ticket for \$75, which is the most you were willing to pay. While you are in line to enter the concert hall, someone offers you \$90 for the ticket. Would you sell the ticket? Would an economist think it is rational to sell the ticket? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 400** at the end of this chapter.

We begin this chapter by exploring how consumers make decisions. We have seen that economists usually assume that people act in a rational, self-interested way. In explaining consumer behavior, economists believe people make choices that will leave them as satisfied as possible, given their *tastes*, their *incomes*, and the *prices* of the goods and services available to them. We will see how downward-sloping demand curves result from the economic model of consumer behavior. We will also explore how in certain situations, knowing which decision is the best one can be difficult. In these cases, economic reasoning provides a powerful tool for consumers to improve their decision making. Finally, we will see that *experimental economics* has shown that factors such as social pressure and notions of fairness can affect consumer behavior. We will look at how businesses take these factors into account when setting prices. In the appendix to this chapter, we extend the analysis by using indifference curves and budget lines to understand consumer behavior.

10.1

Utility and Consumer Decision Making

LEARNING OBJECTIVE: Define utility and explain how consumers choose goods and services to maximize their utility.

We have seen that the model of demand and supply is a powerful tool for analyzing how prices and quantities are determined. We have also seen that, according to the *law of demand*, whenever the price of a good falls, the quantity demanded increases. In this section, we will show how the economic model of consumer behavior leads to the law of demand.

An Overview of the Economic Model of Consumer Behavior

Imagine walking through a shopping mall, trying to decide how to spend your clothing budget. If you had an unlimited budget, your decision would be easy: Just buy as much of everything as you want. Given that you have a limited budget, what do you do? Economists assume that consumers act so as to make themselves as well off as possible. Therefore, you should choose the one combination of clothes that makes you as well off as possible from among those combinations that you can afford. Stated more generally, the economic model of consumer behavior predicts that consumers will choose to buy the combination of goods and services that makes them as well off as possible from among all the combinations that their budgets allow them to buy.

Although this prediction may seem obvious and not particularly useful, we will see that it leads to conclusions that are useful—but not obvious. [MyEconLab Concept Check](#)

Utility

The amount of satisfaction you receive from consuming a particular combination of goods and services depends on your tastes or preferences. There is an old saying—“There’s no accounting for taste”—and economists don’t try to. If you buy a can of Red Bull energy drink instead of a can of Monster Energy, even though Monster Energy has a lower price, you must receive more enjoyment or satisfaction from drinking Red Bull. Economists refer to the enjoyment or satisfaction people receive from consuming goods and services as **utility**. So we can say that the goal of a consumer is to spend available income so as to maximize utility. But utility is a difficult concept to measure because there is no way of knowing exactly how much enjoyment or satisfaction someone receives from consuming a product. Similarly, it is not possible to compare utility across consumers. There is no way of knowing for sure whether Jill receives more or less satisfaction than Jack from drinking a can of Red Bull.

Two hundred years ago, economists hoped to measure utility in units called *utils*. The util would be an objective measure in the same way that temperature is: If it is 75 degrees in New York and 75 degrees in Los Angeles, it is just as warm in both cities. These economists wanted to say that if Jack’s utility from drinking a can of Red Bull is

Utility The enjoyment or satisfaction people receive from consuming goods and services.

10 utils and Jill's utility is 5 utils, then Jack receives exactly twice the satisfaction from drinking a can of Red Bull as Jill does. In fact, it is *not* possible to measure utility across people. It turns out that none of the important conclusions of the economic model of consumer behavior depend on utility being directly measurable (a point we demonstrate in the appendix to this chapter). Nevertheless, the economic model of consumer behavior is easier to understand if we assume that utility is something directly measurable, like temperature.

MyEconLab Concept Check

The Principle of Diminishing Marginal Utility

To make the model of consumer behavior more concrete, let's see how a consumer makes decisions in a case involving just two products: pizza and Coke. To begin, consider how the utility you receive from consuming a good changes with the quantity of the good you consume. Suppose that you have just arrived at a Super Bowl party where the hosts are serving pizza and you are very hungry. In this situation, you are likely to receive quite a lot of enjoyment, or utility, from consuming the first slice of pizza. Suppose this satisfaction is measurable and is equal to 20 units of utility, or utils. After eating the first slice, you decide to have a second slice. Because you are no longer as hungry, the satisfaction you receive from eating the second slice of pizza is less than the satisfaction you received from eating the first slice. Consuming the second slice increases your utility by only an *additional* 16 utils, which raises your *total* utility from eating the 2 slices to 36 utils. If you continue eating slices, each additional slice gives you less and less additional satisfaction.

The table in Figure 10.1 shows the relationship between the number of slices of pizza you consume while watching the Super Bowl and the amount of utility you receive. The second column in the table shows the total utility you receive from eating a particular number of slices. The third column shows the additional utility, or **marginal utility (MU)**, you receive from consuming one additional slice. (Remember that in economics, *marginal* means *additional*.) For example, as you increase your consumption from 2 slices to 3 slices, your total utility increases from 36 to 46, so your marginal utility from consuming the third slice is 10 utils. As the table shows, by the time you eat the fifth slice of pizza that evening, your marginal utility is very low: only 2 utils. If you were to eat a sixth slice, you would become slightly ill, and your marginal utility would actually be a *negative* 3 utils.

Figure 10.1 also plots the numbers from the table as graphs. Panel (a) shows how your total utility rises as you eat the first 5 slices of pizza and then falls as you eat the sixth slice. Panel (b) shows how your marginal utility declines with each additional slice you eat and finally becomes negative when you eat the sixth slice. The height of the marginal utility line at any quantity of pizza in panel (b) represents the change in utility as a result of consuming that additional slice. For example, the change in utility as a result of consuming 4 slices instead of 3 is 6 utils, so the height of the marginal utility line in panel (b) for the fourth slice is 6 utils.

The relationship illustrated in Figure 10.1 between consuming additional units of a product during a period of time and the marginal utility received from consuming each additional unit is called the **law of diminishing marginal utility**. For nearly every good or service, the more you consume during a period of time, the less you increase your total satisfaction from each additional unit you consume.

MyEconLab Concept Check

The Rule of Equal Marginal Utility per Dollar Spent

The key challenge for consumers is to decide how to allocate their limited incomes among all the products they want to buy. Every consumer has to make trade-offs: If you have \$100 to spend on entertainment for the month, then the more movies you rent or buy online, the fewer movies you can see in the theater. Economists refer to the limited amount of income you have available to spend on goods and services as your **budget constraint**. The principle of diminishing marginal utility helps us understand how consumers can best spend their limited incomes on the products available to them.

Marginal utility (MU) The change in total utility a person receives from consuming one additional unit of a good or service.

Law of diminishing marginal utility The principle that consumers experience diminishing additional satisfaction as they consume more of a good or service during a given period of time.

Budget constraint The limited amount of income available to consumers to spend on goods and services.

Figure 10.1

Total and Marginal Utility from Eating Pizza on Super Bowl Sunday

The table shows that for the first 5 slices of pizza, the more you eat, the more your total satisfaction, or utility, increases. If you eat a sixth slice, you start to feel ill from eating too much pizza, and your total utility falls. Each additional slice increases your utility by less than the previous slice, so your marginal utility from each slice is less than the one before. Panel (a) shows your total utility rising as you eat the first 5 slices and falling with the sixth slice. Panel (b) shows your marginal utility falling with each additional slice you eat and becoming negative with the sixth slice. The height of the marginal utility line at any quantity of pizza in panel (b) represents the change in utility as a result of consuming that additional slice. For example, the change in utility as a result of consuming 4 slices instead of 3 is 6 utils, so the height of the marginal utility line in panel (b) for the fourth slice is 6 utils.

(a) Total utility

(b) Marginal utility

Suppose you attend a Super Bowl party at a restaurant, and you have \$10 to spend on refreshments. Pizza is selling for \$2 per slice, and Coke is selling for \$1 per cup. Table 10.1 shows the relationship between the amount of pizza you eat, the amount of Coke you drink, and the amount of satisfaction, or utility, you receive. The values for pizza are repeated from the table in Figure 10.1. The values for Coke also follow the principle of diminishing marginal utility.

How many slices of pizza and how many cups of Coke should you buy if you want to maximize your utility? If you did not have a budget constraint, you would buy 5 slices of pizza and 5 cups of Coke because that would give you total utility of 107 (=54 + 53), which is the maximum utility you can achieve. Eating another slice of pizza or drinking another cup of Coke during the evening would lower your utility. Unfortunately, you do

have a budget constraint: You have only \$10 to spend. To buy 5 slices of pizza (at \$2 per slice) and 5 cups of Coke (at \$1 per cup), you would need \$15.

To select the best way to spend your \$10, remember this key economic principle: *Optimal decisions are made at the margin.* That is, most of the time economic decision makers—consumers, firms, and the government—are faced with decisions about whether to do a little more of one thing or a little more of an alternative. In this case, you are choosing to consume a little more pizza or a little more Coke. Tesla chooses whether to manufacture more sedans or more SUVs in its California factory. Congress and the president choose whether to spend more for research on heart disease or more to repair highways. Everyone faces a budget constraint, and everyone faces trade-offs.

The key to making the best consumption decision is to maximize utility by following the *rule of equal marginal utility per dollar spent.* As you decide how to spend your income, you should buy pizza and Coke up to the point where the last slice of pizza and the last cup of Coke purchased give you equal increases in utility *per dollar.* By using this approach, you will have maximized your total utility, given your budget constraint.

It is important to remember that to follow this rule, you must equalize your marginal utility per dollar spent, *not* your marginal utility from each good. Buying season tickets for your favorite National Football League (NFL) team or for the symphony or buying a BMW may give you a lot more satisfaction than drinking a cup of Coke, but the NFL tickets may well give you less satisfaction *per dollar spent.* To decide how many slices of pizza and cups of Coke to buy, you must convert the values for marginal utility in Table 10.1 into marginal utility per dollar. You can do this by dividing marginal utility by the price of each good, as shown in Table 10.2.

In column (3), we calculate marginal utility per dollar spent on pizza. Because the price of pizza is \$2 per slice, the marginal utility per dollar from eating 1 slice of pizza

(1) Slices of Pizza	(2) Marginal Utility (MU_{Pizza})	(3) Marginal Utility per Dollar ($\frac{MU_{\text{Pizza}}}{P_{\text{Pizza}}}$)	(4) Cups of Coke	(5) Marginal Utility (MU_{Coke})	(6) Marginal Utility per Dollar ($\frac{MU_{\text{Coke}}}{P_{\text{Coke}}}$)

Table 10.3
Equalizing Marginal Utility per Dollar Spent

Combinations of Pizza and Coke with Equal Marginal Utilities per Dollar	Marginal Utility per Dollar (MU/P)	Total Spending	Total Utility
1 slice of pizza and 3 cups of Coke	10	\$2 + \$3 = \$5	20 + 45 = 65
3 slices of pizza and 4 cups of Coke	5	\$6 + \$4 = \$10	46 + 50 = 96
4 slices of pizza and 5 cups of Coke	3	\$8 + \$5 = \$13	52 + 53 = 105

equals 20 divided by \$2, or 10 utils per dollar. Similarly, we show in column (6) that because the price of Coke is \$1 per cup, the marginal utility per dollar from drinking 1 cup of Coke equals 20 divided by \$1, or 20 utils per dollar. To maximize the total utility you receive, you must make sure that the utility per dollar of pizza for the last slice of pizza is equal to the utility per dollar of Coke for the last cup of Coke. Table 10.2 shows that there are three combinations of slices of pizza and cups of Coke where marginal utility per dollar is equalized. Table 10.3 lists the combinations, the total amount of money needed to buy each combination, and the total utility received from consuming each combination.

Looking at the bottom row of the table, if you buy 4 slices of pizza, the last slice gives you 3 utils per dollar. If you buy 5 cups of Coke, the last cup also gives you 3 utils per dollar, so you have equalized your marginal utility per dollar. Unfortunately, as the third column in the table shows, to buy 4 slices and 5 cups, you would need \$13, and you have only \$10. The top row of the table shows that you could also equalize your marginal utility per dollar by buying 1 slice and 3 cups, but that would cost just \$5, leaving you with \$5 not spent. As the middle row shows, only when you buy 3 slices and 4 cups have you equalized your marginal utility per dollar and spent neither more nor less than the \$10 available.

We can summarize the two conditions for maximizing utility:

$$1. \frac{MU_{\text{Pizza}}}{P_{\text{Pizza}}} = \frac{MU_{\text{Coke}}}{P_{\text{Coke}}}$$

This condition states that the marginal utility per dollar spent must be the same for both goods.

$$2. \text{Spending on pizza} + \text{Spending on Coke} = \text{Amount available to be spent}$$

This condition is the budget constraint, which states that total spending on both goods must equal the amount available to be spent.

Of course, these conditions for maximizing utility apply not just to pizza and Coke but to any pairs of goods.

Finding the Optimal Level of Consumption

The following table shows Lee's utility from consuming ice cream cones and cans of Lime Fizz soda:

0	0	—	0	0	—
1	30	30	1	40	40

4	90	15	4	119	18
5	100	10	5	134	15
6	105	5	6	141	7

- a. Ed inspects this table and concludes, “Lee’s optimal choice would be to consume 4 ice cream cones and 5 cans of Lime Fizz because with that combination, his marginal utility from ice cream cones is equal to his marginal utility from Lime Fizz.” Do you agree with Ed’s reasoning? Briefly explain.
- b. Suppose that Lee has an unlimited budget to spend on ice cream cones and cans of Lime Fizz. Under these circumstances, how many ice cream cones and how many cans of Lime Fizz will he consume? (Assume that Lee cannot consume more than 6 ice cream cones or 6 cans of Lime Fizz.)
- c. Suppose that Lee has \$7 per week to spend on ice cream cones and cans of Lime Fizz. The price of an ice cream cone is \$2, and the price of a can of Lime Fizz is \$1. If Lee wants to maximize his utility, how many ice cream cones and how many cans of Lime Fizz should he buy?

Solving the Problem

- Step 1: Review the chapter material.** This problem involves finding the optimal consumption of two goods, so you may want to review the section “The Rule of Equal Marginal Utility per Dollar Spent,” which begins on page 379.
- Step 2: Answer part (a) by analyzing Ed’s reasoning.** Ed’s reasoning is incorrect. To maximize utility, Lee needs to equalize marginal utility *per dollar* for the two goods.
- Step 3: Answer part (b) by determining how Lee would maximize utility with an unlimited budget.** With an unlimited budget, consumers maximize utility by continuing to buy each good as long as their utility is increasing. In this case, Lee will maximize utility by buying 6 ice cream cones and 6 cans of Lime Fizz, given that we are assuming he cannot buy more than 6 units of either good.
- Step 4: Answer part (c) by determining Lee’s optimal combination of ice cream cones and cans of Lime Fizz.** Lee will maximize his utility if he spends his \$7 per week so that the marginal utility of ice cream cones divided by the price of ice cream cones is equal to the marginal utility of Lime Fizz divided by the price of Lime Fizz. We can use the following table to solve this part of the problem:

Quantity	Ice Cream Cones		Cans of Lime Fizz	
	<i>MU</i>	$\frac{MU}{P}$	<i>MU</i>	$\frac{MU}{P}$
1	30	15	40	40
2	25	12.5	35	35
3	20	10	26	26
4	15	7.5	18	18
5	10	5	15	15
6	5	2.5	7	7

Lee will maximize his utility by buying 1 ice cream cone and 5 cans of Lime Fizz. At this combination, the marginal utility of each good divided by its price equals 15. He has also spent all of his \$7.

What if the Rule of Equal Marginal Utility per Dollar Does Not Hold?

The idea of getting the maximum utility by equalizing the ratio of marginal utility to price for the goods you are buying can be difficult to grasp, so it is worth thinking about in another way. Suppose that instead of buying 3 slices of pizza and 4 cups of Coke, you buy 4 slices and 2 cups. This combination costs \$10, so you would meet your

Don't Let This Happen to You

Equalize Marginal Utilities *per Dollar*

Harry likes to read e-books and watch movies on his tablet. The following table gives Harry's utility from buying books and movies:

Quantity of Books	Total Utility from Books	Marginal Utility from Last Book	Quantity of Movies	Total Utility from Movies	Marginal Utility from Last Movie
0	0	—	0	0	—
1	50	50	1	60	60
2	85	35	2	105	45
3	110	25	3	145	40
4	130	20	4	175	30
5	140	10	5	195	20
6	145	5	6	210	15

Can you determine from this table the optimal combination of books and movies for Harry? It is very tempting to say that Harry should buy 4 books and 5 movies because his marginal utility from books is equal to his marginal utility from movies with that combination. In fact, we can't be sure this is the best combination because we are lacking some critical information: Harry's budget

constraint—how much he has available to spend on books and movies—and the prices of books and movies.

Let's say that Harry has \$100 to spend this month, the price of an e-book is \$10, and the price of an online movie is \$20. Using the information from the first table, we can now calculate Harry's marginal utility per dollar for both goods, as shown in the following table:

Quantity of Books	Marginal Utility from Last Book (MU_{Books})	Marginal Utility per Dollar ($\frac{MU_{Books}}{P_{Books}}$)	Quantity of Movies	Marginal Utility from Last Movie (MU_{Movies})	Marginal Utility per Dollar ($\frac{MU_{Movies}}{P_{Movies}}$)
1	50	5	1	60	3
2	35	3.5	2	45	2.25
3	25	2.5	3	40	2
4	20	2	4	30	1.5
5	10	1	5	20	1
6	5	0.5	6	15	0.75

Harry's marginal utility per dollar is the same for two combinations of books and movies, as shown in the following table:

Combinations of Books and Movies with Equal Marginal Utilities per Dollar	Marginal Utility per Dollar (MU/P)	Total Spending	Total Utility
5 books and 5 movies	1	\$50 + \$100 = \$150	140 + 195 = 335
4 books and 3 movies	2	\$40 + \$60 = \$100	130 + 145 = 275

Unfortunately, 5 books and 5 movies would cost Harry \$150, and he has only \$100. The best Harry can do is to buy 4 books and 3 movies. This combination provides him with the maximum amount of utility attainable, given his budget constraint.

The key point is the same as in Solved Problem 10.1 on page 382: Consumers maximize their utility when they

equalize marginal utility *per dollar* for every good they buy, *not* when they equalize marginal utility.

budget constraint by spending all the money available to you, but would you have gotten the maximum amount of utility? No, you wouldn't have. From the information in Table 10.2 on page 381, we can list the additional utility per dollar you are getting from the last slice and the last cup and the total utility from consuming 4 slices and 2 cups:

- Marginal utility per dollar for the fourth slice of pizza = 3 utils per dollar
- Marginal utility per dollar for the second cup of Coke = 15 utils per dollar
- Total utility from 4 slices of pizza and 2 cups of Coke = 87 utils

Obviously, the marginal utilities per dollar are not equal. The last cup of Coke gave you considerably more satisfaction per dollar than did the last slice of pizza. You could raise your total utility by buying less pizza and more Coke. Buying 1 less slice of pizza frees up \$2 that will allow you to buy 2 more cups of Coke. Eating 1 less slice of pizza reduces your utility by 6 utils, but drinking 2 additional cups of Coke raises your utility by 15 utils (make sure you see this), for a net increase of 9. You end up equalizing your marginal utility per dollar (5 utils per dollar for both the last slice and the last cup) and raising your total utility from 87 to 96 utils.

The Income Effect and Substitution Effect of a Price Change

We can use the rule of equal marginal utility per dollar to analyze how consumers adjust their buying decisions when a price changes. Suppose you are back at the restaurant for the Super Bowl party, but this time the price of pizza is \$1.50 per slice, rather than \$2. You still have \$10 to spend on pizza and Coke.

When the price of pizza was \$2 per slice and the price of Coke was \$1 per cup, your optimal choice was to consume 3 slices of pizza and 4 cups of Coke. The fall in the price of pizza to \$1.50 per slice has two effects on the quantity of pizza you consume.

The Income Effect When the price of a good falls, you have more purchasing power. In our example, 3 slices of pizza and 4 cups of Coke now cost a total of only \$8.50 instead of \$10.00. An increase in purchasing power is essentially the same thing as an increase in income. The change in the quantity of pizza you will demand because of this increase in purchasing power—holding all other factors constant—is the **income effect** of the price change. Recall that if a product is a *normal good*, a consumer increases the quantity demanded as the consumer's income rises, but if a product is an *inferior good*, a consumer decreases the quantity demanded as the consumer's income rises (see Chapter 3). So, if we assume that pizza is a normal good for you, the income effect of a fall in price causes you to consume more pizza. If pizza were an inferior good for you, the income effect of a fall in the price would have caused you to consume less pizza.

The Substitution Effect When the price of pizza falls, pizza becomes cheaper *relative* to Coke, and the marginal utility per dollar for each slice of pizza you consume increases. If we hold constant the effect of the price change on your purchasing power and just focus on the effect of the price being lower relative to the price of the other good, we have isolated the **substitution effect** of the price change. The lower price of pizza relative to the price of Coke has lowered the *opportunity cost* to you of consuming pizza because now you have to give up less Coke to consume the same quantity of pizza. Therefore, the substitution effect from the fall in the price of pizza relative to the price of Coke causes you to eat more pizza and drink less Coke. In this case, both the income effect and the substitution effect of the fall in price cause you to eat more pizza. If the price of pizza had risen, both the income effect and the substitution effect would have caused you to eat less pizza. Table 10.4 summarizes the effect of a price change on the quantity demanded.

We can use Table 10.5 to determine the effect of the fall in the price of pizza on your optimal consumption. Table 10.5 has the same information as Table 10.2, with one change: The marginal utility per dollar from eating pizza has been changed to

Income effect The change in the quantity demanded of a good that results from the effect of a change in price on consumer purchasing power, holding all other factors constant.

Substitution effect The change in the quantity demanded of a good that results from a change in price making the good more or less expensive relative to other goods, holding constant the effect of the price change on consumer purchasing power.

reflect the new lower price of \$1.50 per slice. Examining the table, we can see that the fall in the price of pizza will result in you eating 1 more slice of pizza, so your optimal consumption now becomes 4 slices of pizza and 4 cups of Coke. You will be spending all of your \$10, and the last dollar you spend on pizza will provide you with about the same marginal utility per dollar as the last dollar you spend on Coke. You will not be receiving exactly the same marginal utility per dollar spent on the two products. As Table 10.5 shows, the last slice of pizza gives you 4 utils per dollar, and the last cup of Coke gives you 5 utils per dollar. But this is as close as you can come to equalizing marginal utility per dollar for the two products, unless you can buy a fraction of a slice of pizza or a fraction of a cup of Coke.

10.2 Where Demand Curves Come From

LEARNING OBJECTIVE: Use the concept of utility to explain the law of demand.

According to the *law of demand*, whenever the price of a product falls, the quantity demanded increases (see Chapter 3). Now that we have covered the concepts of total utility, marginal utility, and the budget constraint, we can look more closely at why the law of demand holds.

In our example of optimal consumption of pizza and Coke at the Super Bowl party, we found the following:

$$\text{Price of pizza} = \$2 \text{ per slice} \rightarrow \text{Quantity of pizza demanded} = 3 \text{ slices}$$

$$\text{Price of pizza} = \$1.50 \text{ per slice} \rightarrow \text{Quantity of pizza demanded} = 4 \text{ slices}$$

Figure 10.2 Deriving the Demand Curve for Pizza

A consumer responds optimally to a fall in the price of a product by consuming more of that product. In panel (a), the price of pizza falls from \$2 per slice

to \$1.50, and the optimal quantity of slices consumed rises from 3 to 4. When we graph this result in panel (b), we have the consumer's demand curve.

In panel (a) of Figure 10.2, we plot the two points showing the optimal number of slices of pizza you choose to consume at each price. In panel (b), we draw a line connecting the two points. This downward-sloping line represents your demand curve for pizza. We could find more points on the line by changing the price of pizza and using the information in Table 10.2 to find the new optimal number of slices of pizza you would demand at each price.

To this point in the chapter, we have been looking at an individual demand curve. Economists, though, are typically interested in market demand curves. We can construct the market demand curve from the individual demand curves for all the consumers in the market. To keep things simple, let's assume that there are only three consumers in the market for pizza: you, David, and Lori. The table in Figure 10.3 shows the individual demand schedules for the three consumers. Because consumers differ in their incomes and their preferences for products, we would not expect every consumer to demand the same quantity of a given product at each price. The final column gives the market demand, which is simply the sum of the quantities demanded by each of the three consumers at each price. For example, at a price of \$1.50 per slice, your quantity demanded is 4 slices, David's is 6 slices, and Lori's is 5 slices. So, at a price of \$1.50, a quantity of 15 slices is demanded in the market. The graphs in the figure show that we can obtain the market demand curve by adding horizontally the individual demand curves.

Remember that according to the law of demand, market demand curves always slope downward. We now know that this result holds because the income and substitution effects of a decrease in price cause consumers to increase the quantity of the good they demand. There is a complicating factor, however. As we discussed earlier, only for a normal good will the income effect lead consumers to increase the quantity of the good they demand when the price falls. For an inferior good, the income effect leads consumers to *decrease* the quantity of the good they demand. The substitution effect, on the other hand, results in consumers increasing the quantity they demand of both normal and inferior goods when the price falls. So, when the price of an inferior good falls, the income effect and substitution effect work in opposite directions: The income effect causes consumers to decrease the quantity of the good they demand, while the substitution effect causes consumers to increase the quantity of the good they demand. Is it possible, then, that consumers might actually buy less of a good when the price falls? If they did, the demand curve would be upward sloping.

Figure 10.3 Deriving the Market Demand Curve from Individual Demand Curves

The table shows that the total quantity demanded in a market is the sum of the quantities demanded by each buyer. We can find the market demand curve by adding horizontally the individual demand curves in panels (a), (b), and (c).

For instance, at a price of \$1.50, your quantity demanded is 4 slices, David's is 6 slices, and Lori's is 5 slices. Therefore, panel (d) shows that a price of \$1.50 and a quantity demanded of 15 is a point on the market demand curve.

Are There Any Upward-Sloping Demand Curves in the Real World?

For a demand curve to be upward sloping, the good would have to be an inferior good, and the income effect would have to be larger than the substitution effect. Economists have understood the conditions for an upward-sloping demand curve since the possibility was first discussed by the British economist Alfred Marshall in the 1890s. Marshall wrote that his friend, Sir Robert Giffen, had told him that when the price of bread rose, very poor people in British cities would actually buy more bread rather than less. Since that time, goods with upward-sloping demand curves have been referred to as *Giffen goods*.

For more than a century, finding an actual Giffen good proved impossible. A close examination of the data showed that Giffen had been mistaken and that poor people in British cities bought less bread when prices rose, so their demand curves were downward sloping. Other possible candidates for being Giffen goods were also found to actually have downward-sloping demand curves. Finally, in 2006, Robert Jensen of Brown University and Nolan Miller of Harvard discovered two Giffen goods. They reasoned that to be a Giffen good, with an income effect larger than its substitution effect, a good must be inferior and make up a very large portion of consumers' budgets. Jensen and Miller knew that very poor people in the Hunan region of China spent most of their incomes on rice, while in the Gansu province, very poor people spent most of their income on wheat-based foods, such as buns and noodles. In both places, poor people

ate meat when their incomes made it possible because they preferred the taste of meat, even though it did not supply as many calories as the rice or wheat they could purchase for the same price.

Jensen and Miller carried out the following experiment: In Hunan, for a five-month period, they gave a selected number of poor families coupons that would allow them to buy rice at a lower price. Families could not use the coupons for any other purpose. In Gansu, they gave a selected number of poor families coupons to buy wheat at a lower price. Jensen and Miller then observed the purchases of the families during the time they received the coupons and during the period immediately thereafter. In Hunan, during the months they received the coupons, the families bought less rice and more meat, and in Gansu, they bought less wheat and more meat. Because in Hunan, families bought less rice when the price was lower, their demand curves for rice were upward sloping. Similarly, in Gansu, families bought less wheat when the price was lower, so their demand curves for wheat were upward sloping. After more than a century of searching, economists had finally discovered examples of a Giffen good.

Social Influences on Decision Making

LEARNING OBJECTIVE: Explain how social influences can affect consumption choices.

Sociologists and anthropologists have argued that social factors such as culture, customs, and religion are very important in explaining the choices people make. Economists have traditionally seen such factors as being relatively unimportant, if they take them into consideration at all. Recently, however, some economists have begun to study how social factors influence consumer choice.

For example, people seem to receive more utility from consuming goods they believe are popular. As the economists Gary Becker, a Nobel Prize winner in economics, and Kevin Murphy put it:

The utility from drugs, crime, going bowling, owning a Rolex watch, voting Democratic, dressing informally at work, or keeping a neat lawn depends on whether friends and neighbors take drugs, commit crimes, go bowling, own Rolex watches, vote Democratic, dress informally, or keep their lawns neat.

This reasoning can help explain why one restaurant is packed, while another restaurant that serves essentially the same food and has similar decor has many fewer customers. Consumers decide which restaurant to go to not only on the basis of food and decor but also on the basis of the restaurant’s popularity. People receive utility from being seen eating at a popular restaurant because they believe it makes them appear knowledgeable and fashionable. Whenever consumption takes place publicly, some consumers base their purchasing decisions on what other consumers are buying. Examples of public consumption include eating in restaurants, attending sporting events, wearing clothes or jewelry, and driving cars. In all these cases, the decision to buy a product depends partly on the characteristics of the product and partly on how many other people are buying the product.

The Effects of Celebrity Endorsements

In many cases, it is not just the number of people who use a product that makes it desirable but the types of people who use it. If consumers believe that media stars or professional athletes use a product, demand for the product will often increase. For example, New England Patriots quarterback Tom Brady is one of the biggest stars in the National Football League, so it may not be surprising that companies including

Glaceau Smartwater, Movado watches, Under Armour sportswear, and UGG footwear have lined up to have him endorse their products. Brady makes around \$7 million per year from his endorsements.

Tom Brady is a great football player, but why do consumers care what products he uses? They may believe Brady has better information than they do about the products he endorses. The average football fan might believe that if Brady endorses Under Armour sportswear, maybe Under Armour makes better sportswear. It seems more likely, however, that people buy products associated with Tom Brady or other celebrities because using these products makes them feel closer to the celebrity endorser or because it makes them appear to be fashionable.

MyEconLab **Concept Check**

Network externality A situation in which the usefulness of a product increases with the number of consumers who use it.

Network Externalities

Technology can play a role in explaining why consumers buy products that many other consumers are already buying. There is a **network externality** in the consumption of a product if the usefulness of the product increases with the number of consumers who use it.

There's Strength in Numbers If you owned the only phone in the world, it would not be very useful. The usefulness of phones increases as the number of people who own them increases. Similarly, your willingness to buy an Apple iPad depends in part on the number of other people who own iPads. The more people who own iPads, the more applications, or “apps,” other firms will produce for the iPad, and the more novels, textbooks, newspapers, and magazines publishers will make available for downloading to the iPad, and, therefore, the more useful an iPad is to you.

Do Switching Costs Cause Inferior Technologies to Survive? Some economists have suggested the possibility that network externalities may have a significant downside because they might result in consumers buying products that contain inferior technologies. This outcome could occur because network externalities can create significant *switching costs* related to changing products: When a product becomes established, consumers may find switching to a new product that contains a better technology too costly. The selection of products may be *path dependent*: Because of switching costs, the technology that was first available may have advantages over better technologies that were developed later. In other words, the path along which the economy has developed in the past is important.

One possible example of path dependence and the use of an inferior technology is the QWERTY order of the letters along the top row of most computer keyboards. This order became widely used when manual typewriters were developed in the late nineteenth century. The metal keys on manual typewriters would stick together if a user typed too fast, so the QWERTY keyboard was designed to slow down typists and minimize the problem of the keys sticking together. With computers, the problem that QWERTY was developed to solve no longer exists, so keyboards could be changed to have letters in a more efficient layout. But because the overwhelming majority of people have learned to use keyboards with the QWERTY layout, there might be significant costs to them if they had to switch, even if a new layout ultimately made them faster typists.

Other products that supposedly embodied inferior technologies are VHS video recorders—supposedly inferior to Sony Betamax recorders—and the Windows computer operating system—supposedly inferior to the Macintosh operating system.

Do Network Externalities Result in Market Failures? Some economists have argued that because of path dependence and switching costs, network externalities can result in *market failures*, which are situations in which the market fails to produce the efficient level of output (see Chapter 5). If network externalities result in market failure, government intervention in these markets might improve economic efficiency. Many economists are skeptical, however, that network externalities really do lead to consumers being locked into products with inferior technologies. In particular, economists Stan Leibowitz of the University of Texas, Dallas, and Stephen Margolis of

North Carolina State University have argued that, in practice, the gains from using a superior technology are larger than the losses due to switching costs. After carefully studying the cases of the QWERTY keyboard, VHS video recorders, and the Windows computer operating system, they have concluded that there is no good evidence that the alternative technologies were actually superior. The implications of network externalities for economic efficiency remain controversial among economists. [MyEconLab](#) [Concept Check](#)

Does Fairness Matter?

If people were only interested in making themselves as well off as possible in a material sense, they would not be concerned with fairness. There is a great deal of evidence, however, that people like to be treated fairly and that they usually attempt to treat others fairly, even if doing so makes them worse off financially. Tipping servers in restaurants is an example. In the United States, diners in restaurants typically add 15 to 20 percent to their food bills as tips to their servers. Tips are not *required*, but most people consider not tipping to be very unfair, unless the service has been exceptionally bad. You could argue that people leave tips not to be fair but because they are afraid that if they don't leave a tip, the next time they visit the restaurant, they will receive poor service. Studies have shown, however, that most people leave tips at restaurants even while on vacation or in other circumstances where they are unlikely to visit the restaurant again.

There are many other examples where people willingly part with money when they are not required to do so and when they receive nothing material in return. The most obvious example is making donations to charity. Apparently, donating money to charity or leaving tips in restaurants that they will never visit again gives people more utility than they would receive from keeping the money and spending it on themselves.

A Test of Fairness in the Economic Laboratory: The Ultimatum Game Experiment Economists have used experiments to understand the role that fairness plays in consumer decision making. *Experimental economics* has been widely used during the past two decades, and a number of experimental economics laboratories exist in the United States and Europe. Economists Maurice Allais, Reinhard Selten, and Vernon Smith were awarded the Nobel Prize in Economics in part because of their contributions to experimental economics. Experiments make it possible to focus on a single aspect of consumer behavior. The *ultimatum game*, first popularized by Werner Güth of the Max Planck Institute of Economics in Germany, is an experiment that tests whether fairness is important in consumer decision making. Various economists have conducted the ultimatum game experiment under slightly different conditions but with generally the same result.

Figure 10.4 illustrates the ultimatum game. A group of volunteers—often college students—are divided into pairs. One member of each pair is the “allocator,” and the other member of the pair is the “recipient.” Each pair is given an amount of money, say \$20. The allocator decides how much of the \$20 each member of the pair will get. There are no restrictions on how the allocator divides up the money. The allocator could keep it all, give it all to the recipient, or anything in between. The recipient must then decide whether to accept the allocation or reject it. If the recipient decides to accept the

[MyEconLab](#) [Animation](#)

Figure 10.4

The Ultimatum Game

In the ultimatum game, an allocator divides an amount of money between himself or herself and the recipient. If the recipient rejects the division of money, neither player receives anything. In experiments, most recipients would rather receive nothing than receive what they believe to be an unfair division of the money.

allocation, each member of the pair gets to keep his or her share. If the recipient decides to reject the allocation, both members of the pair receive nothing.

If neither the allocator nor the recipient cares about fairness, optimal play in the ultimatum game is straightforward: The allocator should propose a division of the money in which the allocator receives \$19.99 and the recipient receives \$0.01. The allocator has maximized his or her gain. The recipient should accept the division because the alternative is to reject it and receive nothing at all: Even a penny is better than nothing. In fact, when the ultimatum game experiment is carried out, both allocators and recipients act as if fairness is important. Allocators usually offer recipients at least a 40 percent share of the money, and recipients almost always reject offers of less than a 10 percent share.

Why do allocators offer recipients more than a negligible amount? It might be that allocators do not care about fairness but fear that recipients do care and will reject offers they consider unfair. This possibility was tested in an experiment known as the *dictator game* carried out by Daniel Kahneman (a psychologist who shared the Nobel Prize in Economics), Jack Knetsch, and Richard Thaler, using students at Cornell University. In this experiment, the allocators were given only two possible divisions of \$20: either \$18 for themselves and \$2 for the recipient or an even division of \$10 for themselves and \$10 for the recipient. One important difference from the ultimatum game was that *the recipient was not allowed to reject the division*. Of the 161 allocators, 122 chose the even division of the \$20. Because there was no possibility of the \$18/\$2 split being rejected, the allocators must have chosen the even split because they valued acting fairly.

Why would recipients in the ultimatum game ever reject any division of the money in which they receive even a very small amount, given that even a small amount of money is better than nothing? Apparently, most people value fairness enough that they will refuse to participate in transactions they consider unfair, even if they are worse off financially as a result.

Are the Results of Economic Experiments Reliable? Economists have conducted the ultimatum game and the dictator game many times in different countries using different groups of people. Therefore, most economists believe that the results of the game provide strong evidence that people value fairness. Recently, however, some economists have begun to question this conclusion. They argue that the experimental situation is artificial, so results may not hold up in the real world. Although allocators in the dictatorship game give money to the other player, whose identity is not known to the allocator, in the real world, people rarely just hand money to strangers. So, it is possible that the fairness observed in the experiments may be the result of people wanting to avoid appearing selfish rather than people valuing fairness. For instance, in the ultimatum game, anyone who kept \$19.99 and gave the other person only \$0.01 might be afraid of appearing selfish in the eyes of the economist conducting the experiment. Particularly because the dollar amounts in the experiment are small, wanting to please the person conducting the experiment may be the main motive behind the choices made.

There is some experimental evidence that when the amount being divided is large, recipients in ultimatum games will accept even very uneven divisions. Steffen Andersen of the Copenhagen Business School and colleagues conducted the dictator game with poor villagers in India, whose average daily wage was about 100 rupees. In their experiments, the amounts to be divided varied from 20 rupees to 20,000 rupees. They found that the larger the amount at stake, the smaller the share the allocator offered the recipient. When the amount was 20,000 rupees—or the equivalent of about 200 days' pay—allocators offered recipients on an average a share of about 12 percent. Despite being offered this low share, only 4 percent of recipients rejected the offer. The results indicate that, as economists might expect, the more costly it is to a recipient to reject an unfair offer, the less likely the recipient is to do so.

John List of the University of Chicago has carried out the following versions of the dictator game:

Version 1: When List gave every player \$5 and followed the usual procedure of having half the players act as dictators in dividing up the \$5, he found the usual result, with 71 percent of dictators allocating some money to the other player.

Version 2: When List gave the dictator the choice of either giving money to the other player or *taking* up to \$5 from the other player, only 10 percent of dictators gave the other player any money, and more than half the dictators took money from the other player.

Version 3: When List asked players to work for 30 minutes at a simple task to earn the \$5 before playing the game, two-thirds of the dictators neither gave anything to nor took anything from the other player. This last result may indicate that the source of the money being allocated matters.

This recent research does not completely reverse the usual interpretation of the results of the ultimatum and dictator games. However, the research does show that the results of the games are not as clear-cut as many economists had thought. It also shows that adjusting one detail of an economic experiment can have a significant effect on its results.

Business Implications of Fairness If consumers value fairness, how does this affect firms? One consequence is that firms will sometimes not raise prices of goods and services, even when there is a large increase in demand, because they are afraid their customers will consider the price increases unfair and may buy elsewhere.

Consider three examples where it seems that businesses could increase their profits by raising prices:

- When the dance rock band LCD played a concert at New York's Madison Square Garden, the tickets were priced at \$50 each. But, demand for the tickets was so high that tickets sold online for as much as \$2,500 each. Why didn't the band or the concert promoter charge more than \$50 for the tickets?
- Each year, many more people would like to buy tickets to see the Super Bowl than there are tickets for them to buy at the price the National Football League (NFL) charges. Why doesn't the NFL raise prices?
- When the restaurant Next opened in Chicago, it used a unique approach to pricing. The restaurant sold tickets that entitled the buyer to a dinner, including drinks and tip. The restaurant sold the tickets for \$45 to \$75, depending on the dinner chosen. The tickets were resold online for prices from \$500 to \$3,000. Why didn't Next increase its ticket prices?

In each of these cases, it appears that a firm could increase its profits by raising prices. The seller would be selling the same quantity—of seats at a concert or in a football stadium, or meals in a restaurant—at a higher price, so profits should increase. Economists have provided two explanations for why firms sometimes do not raise prices in these situations. Gary Becker has suggested that the products involved—concerts, football games, or restaurant meals—are all products that buyers consume together with other buyers. In those situations, the amount consumers wish to buy may be related to how much of the product other people are consuming. People like to consume, and be seen consuming, a popular product—ones where the quantity demanded appears to be much greater than the quantity supplied. If rock bands, the NFL, and popular restaurants increased their prices enough to equate the quantity of tickets demanded with the quantity supplied, they might find that they had also eliminated their popularity.

Daniel Kahneman, Jack Knetsch, and Richard Thaler have offered another explanation for why firms don't always raise prices when doing so would seem to increase their profits. In surveys of consumers, these researchers found that most people considered it fair for firms to raise their prices following an increase in costs but unfair to raise prices following an increase in demand. For example, Kahneman, Knetsch, and Thaler conducted a survey in which people were asked their opinion of the following situation: "A hardware store has been selling snow shovels for \$15. The morning after a large snowstorm, the store raises the price to \$20." Eighty-two percent of respondents said that they considered the hardware store's actions to be unfair. Kahneman, Knetsch, and Thaler have concluded that firms may sometimes not raise their prices even when

the quantity demanded of their product is greater than the quantity supplied out of fear that, in the long run, they will lose customers who believe the price increases were unfair.

In analyzing the pricing of Super Bowl tickets, economist Alan Krueger of Princeton University provided some support for Kahneman, Knetsch, and Thaler's explanation of why companies do not always raise prices when the quantity demanded is greater than the quantity supplied. In 2015, the NFL charged \$2,000 for the best seats at the Super Bowl and at least \$800 for the other seats. Many of these tickets were resold online for as much as \$10,000 each. Krueger surveyed football fans attending the game to see if their views could help explain why the NFL didn't charge higher prices for the tickets. In the year he conducted the survey, the face value of Super Bowl tickets was \$325 to \$400. When asked whether it would "be fair for the NFL to raise the [price of tickets] to \$1,500 if that is still less than the amount most people are willing to pay for tickets," 92 percent of the fans surveyed answered "no." Even 83 percent of the fans who had paid more than \$1,500 for their tickets answered "no." Krueger concluded that whatever the NFL might gain in the short run from raising ticket prices, it would more than lose in the long run by alienating football fans.

These explanations for why firms don't always raise prices to a level that would equate the quantity demanded with the quantity supplied share the same basic idea: Sometimes firms will give up some profits in the short run to keep their customers happy and increase their profits in the long run.

Is Uber Price Gouging?

The Uber mobile app has become very popular. Rather than call or flag down a taxi for a ride home after a party or a football game, many people use the app to summon a driver who uses his or her own car to provide rides. Many consumers prefer Uber because they believe Uber drivers are more reliable in responding and arrive faster than taxis, particularly in smaller cities where taxi service is not always dependable. In addition, some consumers find Uber's payment system to be convenient. Because the user's credit card information is loaded into the app, the price of a trip is automatically billed to the card, and the driver does not have to be tipped. Business travelers also use Uber. In 2015, business travelers were making about 33 percent as many trips using Uber as using a taxi, up from only 11 percent one year earlier.

Travis Kalanick and Garrett Camp founded Uber in San Francisco in 2009. They believed that the restrictions many local governments placed on taxi services meant that an inefficiently small quantity of taxi rides were being supplied in many markets. Because Uber relies on individuals driving their own cars, it is not legally a taxi service, and so it is not subject to government regulations on taxis. Taxi companies in many cities, though, have protested against Uber because it usually charges prices lower than the local governments allow the taxi companies to charge.

Typically, Uber charges lower prices than taxi companies charge—but not always. Uber sets prices based on the number of people who request rides at a given time in a given area, and it raises prices as demand increases. This "surge pricing" can more than triple normal prices when demand is very high. One rider used Uber to call for a ride on New Year's Eve only to find that instead of the expected price of \$35, the charge would be \$262. Kalanick argues that consumers should think of Uber prices the same way they think of airline ticket prices: "You know that if you buy a flight on the day before Christmas, it's probably 10 times more expensive than two weeks after Christmas." In addition, he argues that increasing prices when demand increases gives drivers—whose pay increases with prices—an incentive to provide rides at busy times, such as New Year's Eve or at a stadium at the end of a football game.

But as the research of Kahneman, Knetsch, and Thaler has shown, consumers see it as more fair for firms to raise prices after an increase in costs than as a result of an increase in demand. Not surprisingly, Uber has come under criticism

Is it "fair" for Uber to charge more when demand for rides is high?

on Facebook and other social networking sites as a result of its surge pricing. Financial writer James Surowiecki suggests that firms such as Uber can avoid this criticism that surge pricing is unfair if they label the surge price the normal price and the lower non-surge price as a discount price. Just as movie theaters label the price they charge for tickets in the evening—when demand is high—the normal ticket price and the price they charge in the afternoon—when demand is low—as a discount from the normal price.

It remains to be seen whether the resentment of some consumers over what they see as Uber's unfair surge pricing will limit the growth of the service.

10.4 Behavioral Economics: Do People Make Their Choices Rationally?

LEARNING OBJECTIVE: Describe the behavioral economics approach to understanding decision making.

When economists say that consumers and firms are behaving “rationally,” they mean that consumers and firms are taking actions that are appropriate to reach their goals, given the information available to them. In recent years, some economists have begun studying situations in which people do not appear to be making choices that are economically rational. This new area of economics is called **behavioral economics**. Why might consumers or businesses not act rationally? The most obvious reason is that they do not realize that their actions are inconsistent with their goals. One of the objectives of economics is to suggest ways to make better decisions. In this section, we discuss ways in which people can improve their decisions by avoiding some common pitfalls. We also use ideas from behavioral economics to analyze how consumers make decisions when shopping.

Behavioral economics The study of situations in which people make choices that do not appear to be economically rational.

Pitfalls in Decision Making

Consumers commonly commit the following three mistakes when making decisions:

1. They take into account monetary costs but ignore nonmonetary opportunity costs that don't involve explicitly spending money.
2. They fail to ignore sunk costs.
3. They are unrealistic about their future behavior.

Ignoring Nonmonetary Opportunity Costs Remember that the **opportunity cost** of any activity is the highest-valued alternative that must be given up to engage in that activity. For example, if you own something you could sell, you incur an opportunity cost if you use it yourself. It is often difficult for people to think of opportunity costs in these terms.

Opportunity cost The highest-valued alternative that must be given up to engage in an activity.

Consider the following example: The NFL ran a lottery that allowed the winners to purchase Super Bowl tickets at their face value, which was either \$325 or \$400, depending on where in the stadium the seats were located. Economist Alan Krueger of Princeton surveyed the lottery winners, asking them two questions:

Question 1: If you had not won the lottery, would you have been willing to pay \$3,000 for your ticket?

Answer 1: Ninety-four percent answered that they would not have paid \$3,000 for a ticket.

Question 2: If after winning your ticket (and before arriving in Florida for the Super Bowl) someone had offered you \$3,000 for your ticket, would you have sold it?

Answer 2: Ninety-two percent answered that they would not have sold their ticket for \$3,000.

But these answers are contradictory! If someone offers you \$3,000 for your ticket, then by using the ticket rather than selling it, you incur an opportunity cost of \$3,000. There really is a \$3,000 cost involved in using that ticket, even though you do not pay \$3,000 in cash. The two alternatives—either paying \$3,000 or not receiving \$3,000—amount to exactly the same thing.

If the ticket is really *not* worth \$3,000 to you, you should sell it. If it is worth \$3,000 to you, you should be willing to pay \$3,000 in cash to buy it. Not being willing to sell a ticket you already own for \$3,000 while at the same time not being willing to buy a ticket for \$3,000 if you didn't already own one is inconsistent behavior. The inconsistency comes from a failure to take into account nonmonetary opportunity costs. Behavioral economists believe this inconsistency is caused by the **endowment effect**, which is the tendency of people to be unwilling to sell a good they already own even if they are offered a price that is greater than the price they would be willing to pay to buy the good if they didn't already own it.

Endowment effect The tendency of people to be unwilling to sell a good they already own even if they are offered a price that is greater than the price they would be willing to pay to buy the good if they didn't already own it.

The failure to take into account opportunity costs is a very common error in decision making. Suppose, for example, that a friend is in a hurry to have his room cleaned—it's the Friday before parents' weekend—and he offers you \$50 to do it for him. You turn him down and spend the time cleaning your own room, even though you know somebody down the hall who would be willing to clean your room for \$20. Leave aside complicating details—the guy who asked you to clean his room is a real slob, or you don't want the person who offered to clean your room for \$20 to go through your stuff—and you should see the point we are making. The opportunity cost of cleaning your own room is \$50—the amount your friend offered to pay you to clean his room. It is inconsistent to turn down an offer from someone else to clean your room for \$20 when you are doing it for yourself at a cost of \$50. The key point here is this: *Nonmonetary opportunity costs are just as real as monetary costs, and people should take them into account when making decisions.*

There are many examples of businesses taking advantage of the tendency of consumers to ignore nonmonetary costs. For example, some firms sell products with mail-in rebates. Rather than have a mail-in rebate of \$10, why not just cut the price by \$10? Companies are relying on the fact that failing to mail in a rebate form once you have already paid for a product is a nonmonetary opportunity cost rather than a direct monetary cost. In fact, only a small percentage of customers actually mail in rebates.

Sunk cost A cost that has already been paid and cannot be recovered.

Failing to Ignore Sunk Costs A **sunk cost** is a cost that has already been paid and cannot be recovered. Once you have paid money and can't get it back, you should ignore that money in any later decisions you make. Consider the following two situations:

Situation 1: You bought a ticket to a play for \$75. The ticket is nonrefundable and must be used on Tuesday night, which is the only night the play will be performed. On Monday, a friend calls and invites you to a local comedy club to see a comedian you both like who is appearing only on Tuesday night. Your friend offers to pay the cost of going to the club.

Situation 2: It's Monday night, and you are about to buy a ticket for the Tuesday night performance of the same play as in situation 1. As you are leaving to buy the ticket, your friend calls and invites you to the comedy club.

Would your decision to go to the play or the comedy club be different in situation 1 than in situation 2? Most people would say that in situation 1, they would go to the play because otherwise they would lose the \$75 they had paid for the ticket. In fact, the \$75 is "lost" no matter what you do because the ticket is nonrefundable. The only real issue for you to decide is whether you would prefer to see the play or prefer to go with your friend to the comedy club. If you would prefer to go to the club, the fact that you have already paid \$75 for the ticket to the play is irrelevant. Your decision should be the same in situation 1 as in situation 2.

Psychologists Daniel Kahneman and Amos Tversky explored the tendency of consumers to *not* ignore sunk costs by asking two samples of people the following questions:

Question 1: One sample of people was asked: “Imagine that you have decided to see a play and have paid the admission price of \$10 per ticket. As you enter the theater, you discover that you have lost the ticket. The seat was not marked, and the ticket cannot be recovered. Would you pay \$10 for another ticket?” Of those asked, 46 percent answered “yes,” and 54 percent answered “no.”

Question 2: A different sample of people was asked: “Imagine that you have decided to see a play where admission is \$10 per ticket. As you enter the theater, you discover that you have lost a \$10 bill. Would you still pay \$10 for a ticket to the play?” Of those asked, 88 percent answered “yes,” and 12 percent answered “no.”

The situations presented in the two questions are actually the same and should have received the same fraction of yes and no responses. Many people, though, have trouble seeing that in question 1, when deciding whether to see the play, they should ignore the \$10 already paid for a ticket because it is a sunk cost.

A Blogger Who Understands the Importance of Ignoring Sunk Costs

In recent years, many people have started blogs—or “Web logs”—where they record their thoughts on politics, sports, their favorite hobbies, or anything else that interests them. Some bloggers can spend hours a day writing up their latest ideas and providing links to relevant material on the Web. A few blogs become so successful that they attract paid advertising and earn their owners a good income. Arnold Kim began blogging about Apple products in 2000 during his fourth year of medical school. He continued blogging on his site, MacRumors.com, over the next eight years, while pursuing a medical career as a nephrologist—a doctor who treats kidney problems.

By 2008, Kim’s site had become very successful, attracting 4.4 million people and more than 40 million page views each month. He was earning more than \$100,000 per year from paid advertising by companies such as Verizon, Audible.com, and CDW. But the tasks of compiling rumors about new Apple products, keeping an Apple buying guide up to date, and monitoring multiple discussion boards on the site became more than he could handle as a part-time job. Kim enjoyed working on the Web site and believed that ultimately it could earn him more than he was earning as a doctor. Still, he hesitated to abandon his medical career because he had invested nearly \$200,000 in his education.

But the \$200,000, as well as the years he had spent in medical school, completing a residency in internal medicine, and completing a fellowship in nephrology, were sunk costs. Kim realized that he needed to ignore these sunk costs in order to make a rational decision about whether to continue in medicine or to become a full-time blogger. After calculating that he would make more from his Web site than from his medical career—and taking into account that by working from home he could spend more time with his young daughter—he decided to blog full time. He was quoted as saying that, “on paper it was an easy decision.” Despite competition from new blogs, MacRumors continued to do well, being viewed by 10 million people per month in mid-2015, and Kim’s income had risen above what he would have made as a doctor.

Knowing that it is rational to ignore sunk costs can be important in making key decisions in life.

Being Unrealistic about Future Behavior Studies have shown that a majority of adults in the United States are overweight. Why do many people choose to eat too much? One possibility is that they receive more utility from eating high-calorie foods than they would from being thin. A more likely explanation, however, is that many people eat a lot today because they expect to eat less tomorrow. But they never do eat less, and so they end up overweight. (Of course, some people also suffer from medical problems that lead to weight gain.) Similarly, some people continue smoking today because they expect to be able to give it up sometime in the future. Unfortunately, for many people that time never comes, and they suffer the health consequences of years of smoking. In both these cases, people are overvaluing the utility from current choices—eating chocolate cake or smoking—and undervaluing the utility to be received in the future from being thin or not getting lung cancer.

Economists who have studied this question argue that many people have preferences that are not consistent over time. In the long run, you would like to be thin or give up smoking or achieve some other goal, but each day, you make decisions (such as to eat too much or smoke) that are not consistent with this long-run goal. If you are unrealistic about your future behavior, you underestimate the costs of choices—such as overeating or smoking—that you make today. A key way of avoiding this problem is to be realistic about your future behavior.

Taking into account nonmonetary opportunity costs, ignoring sunk costs, and being more realistic about future behavior are three ways in which consumers are able to improve the decisions they make.

The Behavioral Economics of Shopping

In Section 10.1, we analyzed how consumers can choose the products they buy so as to maximize utility. In this section, we briefly consider problems consumers may encounter that keep them from making optimal consumption choices.

In discussing how consumers maximize utility, we used simple examples where people were choosing the optimal quantity of two goods subject to a budget constraint. Consider, though, a typical trip to the supermarket. Someone shopping for a family of four might end up buying 25 or more products. A consumer in that situation is unlikely to equate the ratios of the marginal utilities to the prices for all these products when deciding the quantities to buy. Does it matter that consumers often do not make optimal consumption choices? Economists are divided in their answers to this question. Many economists make these two points in arguing that the answer to the question is “no”:

1. The assumptions in most scientific models, including economic models, are not literally correct. In the model of consumer choice, for example, unrealistic assumptions are necessary to simplify a complex reality by focusing on the most important factors involved in decision making.
2. Models are best judged by the success of their predictions rather than by the realism of their assumptions. Predictions based on the model of consumer choice have been successful in predicting many types of consumer behavior.

Rules of Thumb Behavioral economists argue that it *does* matter that consumers usually do not make optimal consumption choices. These economists believe that there are benefits to analyzing *how* consumers actually make decisions. The model we have used in this chapter assumes that:

- When people shop, they have full information on the prices of products, including information on differences in prices across stores.
- People can make complicated calculations such as computing the ratios of marginal utilities to prices across many products.

In fact, people often make choices on the basis of only limited information and without the time or capacity to calculate their optimal choices. As a result, rather than making optimal choices, people often use *rules of thumb*, which are guides to decision

making that may not produce optimal choices. For example, a consumer may decide that a particular supermarket has the lowest prices for the products he or she buys, without continually checking whether this assumption is correct. If a new supermarket with lower prices opens, the consumer, at least for a period, may continue shopping at the old supermarket, even though doing so is no longer optimal.

Anchoring How do shoppers decide whether the price of a product is high or low? Behavioral economists use the word *anchoring* to describe one aspect of how consumers evaluate prices. If people are uncertain about a value, such as a price, they often relate—or anchor—that value to some other known value, even if the second value is irrelevant. Psychologists Amos Tversky and Daniel Kahnemann carried out an experiment to illustrate the effects of anchoring. They constructed a wheel that when spun always stopped on a value of either 10 or 65. They spun the wheel for different participants in the experiment and then asked them: “What is your best guess of the percentage of African nations in the United Nations?” When the wheel stopped on a value of 10, the average answer of the participants was 25 percent. When the wheel stopped on 65, the average answer was 45 percent. Even though the value from the spin of the wheel had no relevance to the question being asked, the value anchored the participants’ responses. In another experiment, conducted by Brian Wansink of Cornell University, Robert Kent of the University of Delaware, and Stephen Hoch of the University of Pennsylvania, three supermarkets offered cans of Campbell’s soup for sale at a 12-percent reduction in price. On one day during the sale, a display sign said “Limit of 12 per person”; on another day, a display sign said “No limit per person.” On the day when the sign limited sales, the supermarkets sold an average of 7 cans per person. On the day when the sign said there was no limit on sales, the supermarkets sold 3.3 cans per person. The number 12 on the sign had anchored the shoppers’ decisions on how many cans to buy.

Consumers often lack the information to evaluate whether the price of a good is “high” or “low.” Stores can take advantage of this lack of information to anchor consumers’ estimates by marking a high “regular price” on a product, which makes the discounted “sale price” appear to be a bargain even if the product is very rarely offered for sale at the regular price.

J.C. Penney Meets Behavioral Economics

We saw at the beginning of this chapter that Ron Johnson, after a very successful career as the head of Apple’s retail stores, was recruited to become the CEO of the J.C. Penney department store chain. Johnson instituted a new pricing strategy of offering goods at “everyday low prices” and rarely discounting prices below those levels. The new strategy turned out to be a failure, as Penney’s revenue declined. Johnson was fired as CEO after only 17 months.

Ideas from behavioral economics can help explain what went wrong. First, Johnson assumed that consumers would understand that the everyday low prices really were low, at least compared with the very high regular prices that Penney had previously used when calculating the discounts it advertised when having a sale. However, there is substantial evidence that some consumers are not well aware of prices even for goods they buy regularly. One study of supermarket shoppers asked people the prices of goods they had just placed in their shopping carts. Fewer than half the shoppers could accurately recall the prices, and one-quarter couldn’t even offer a guess, even though they had placed the goods in their carts less than a minute earlier. Another study asked people who were about to enter a department store questions about the prices of goods they frequently purchased. Only about one-third could give accurate answers. When asked to evaluate whether a specific price of a good they frequently purchased was high or low, about 15 percent of people identified prices that were actually high as being good deals and prices that were actually low as being bad deals.

Consumers generally respond strongly to sales that offer discounted prices, so a strategy that replaces sales with low fixed prices is not likely to be effective.

Studies of retail sales show that consumers purchase a significant fraction of goods at discount prices. For example, a study of checkout scanner data from nine supermarkets showed that while liquid laundry detergent was offered at discount prices only about one-quarter of the time, nearly half of detergent was purchased at the sale prices. Because consumers respond so strongly to sales that offer discounted prices, a strategy that replaces sales with low fixed prices is not likely to be effective.

Why do consumers respond to sales? Why wasn't Penney able to convince consumers that everyday low prices really were low? One possibility is that by displaying both a high "regular price" and a low "sale price," sales provide consumers with an "anchor," or reference point, to interpret the prices being offered. A sale price seems low if offered as a markdown from a higher regular price even if—because of sales and the use of coupons—few people ever buy the good at the regular price. Without the anchor of the regular price, consumers can have difficulty deciding whether an everyday low price is actually low, particularly because some consumers enter a store with little idea of what typical prices are. As the Northwestern professor quoted in the chapter opener put it, "J.C. Penney might say it's a fair price, but why should consumers trust J.C. Penney?"

By largely eliminating sales, Johnson disregarded some of the insights of behavioral economics. As a result, Penney suffered losses, and Johnson lost his job.

Economics in Your Life

Do You Make Rational Decisions?

At the beginning of this chapter, we asked you to consider a situation in which you had paid \$75 for a concert ticket, which is the most you would be willing to pay. Just before you enter the concert hall, someone offers you \$90 for the ticket. We posed two questions: Would you sell the ticket? and Would an economist think it is rational to sell the ticket? If you answered that you would sell, then your answer is rational in the sense in which economists use the term. The cost of going to see the concert is what you have to give up for the ticket. Initially, the cost was just \$75—the dollar price of the ticket. This amount was also the most you were willing to pay. However, once someone offers you \$90 for the ticket, the cost of seeing the concert rises to \$90. The reason the cost of the concert is now \$90 is that once you turn down an offer of \$90 for the ticket, you have incurred a nonmonetary opportunity cost of \$90 if you use the ticket yourself. The endowment effect explains why some people would not sell the ticket. People seem to value something that they own more than something that they do not own. Therefore, a concert ticket you already own may be worth more to you than a concert ticket you have yet to purchase. Behavioral economists study situations like this where people make choices that do not appear to be economically rational.

Conclusion

In a market system, consumers are in the driver's seat. Goods are produced only if consumers want them to be. Therefore, how consumers make their decisions is an important area for economists to study. Economists expect that consumers will spend their incomes so that the last dollar spent on each good provides them with equal additional amounts of satisfaction, or utility. In practice, there are significant social influences on consumer decision making, particularly when a good or service is consumed in public. Fairness also seems to be an important consideration for most consumers. Finally, many consumers could improve the decisions they make if they would take into account nonmonetary opportunity costs, ignore sunk costs, and be more realistic about their future behavior.

In this chapter, we studied consumers' choices. In the next several chapters, we will study firms' choices.

Utility, p. 378

10.1

Utility and Consumer Decision Making, pages 378–386

LEARNING OBJECTIVE: Define utility and explain how consumers choose goods and services to maximize their utility.

Summary

Utility is the enjoyment or satisfaction that people receive from consuming goods and services. The goal of a consumer is to spend available income so as to maximize utility. **Marginal utility** is the change in total utility a person receives from consuming one additional unit of a good or service. The **law of diminishing marginal utility** states that consumers receive diminishing additional satisfaction as they consume more of a good or service during a given period of time. The **budget constraint** is the amount of income consumers have available to spend on goods and services. To maximize utility, consumers should make sure they spend their income so that the last dollar spent on each product gives them the same marginal utility. The **income effect** is the change in the quantity demanded of a good that results from the effect of a change in the price on consumer purchasing power. The **substitution effect** is the change in the quantity demanded of a good that results from a change in price making the good more or less expensive relative to other goods, holding constant the effect of the price change on consumer purchasing power.

Review Questions

- 1.1 What is the economic definition of *utility*? Is it possible to measure utility?
- 1.2 What is the definition of *marginal utility*? What is the law of diminishing marginal utility? Why is marginal utility more useful than total utility in consumer decision making?
- 1.3 Define a consumer's budget constraint and explain why it matters when making optimal consumption decisions.
- 1.4 How does a change in the price of a product cause both a substitution effect and an income effect?

Problems and Applications

- 1.5 Does the law of diminishing marginal utility hold true in every situation? Is it possible to think of goods for which consuming additional units, at least initially, will result in increasing marginal utility?
- 1.6 Does the fact that the last unit of a person's income spent on different products and services should give the same marginal utility imply that people should not save at all? Briefly explain.
- 1.7 You have six hours to study for two exams tomorrow. The following table shows the relationship between hours of study and test scores:

Economics		Psychology	
Hours	Score	Hours	Score
0	54	0	54
1	62	1	60
2	69	2	65
3	75	3	69
4	80	4	72
5	84	5	74
6	87	6	75

- a. Use the rule for determining optimal purchases to decide how many hours you should study each subject. Treat each point on an exam as 1 unit of utility and assume that you consider an extra point on an economics exam to have the same value as an extra point on a psychology exam.
- b. Now suppose that you are a psychology major and that you value each point you earn on a psychology exam as being worth three times as much as each point you earn on an economics exam. Now how many hours should you study each subject?

1.8 (Related to Solved Problem 10.1 on page 382) Joe has \$16 to spend on Twinkies and Ho-Hos. Twinkies have a price of \$1 per pack, and Ho-Hos have a price of \$2 per pack. Use the information in these graphs to determine the number of Twinkies and Ho-Hos packs Joe should buy to maximize his utility. Briefly explain your reasoning.

1.9 (Related to Solved Problem 10.1 on page 382) Joe has \$55 to spend on apples and oranges. Given the information in the following table, is Joe maximizing utility? Briefly explain.

	Price	Quantity	Total Utility	Marginal Utility of Last Unit
Apples	\$0.50	50	1,000	20
Oranges	\$0.75	40	500	30

1.10 Maya spends her \$50 budget on two goods, cans of tuna and bottles of ginger ale. Initially, the marginal utility per dollar she spends on tuna is equal to the marginal utility per dollar she spends on ginger ale. Then the price of ginger ale decreases, while her income and the price of tuna do not change. Briefly explain whether each of the following statements about what happens as a result of the decrease in the price of ginger ale is true or false.

- Her marginal utility from consuming ginger ale increases.
- The marginal utility per dollar she spends on ginger ale increases.
- Because of the substitution effect, Maya will buy more ginger ale. Therefore, we can conclude that ginger ale is a normal good.
- As Maya adjusts to the change in the price of ginger ale, her marginal utility per dollar spent on tuna will increase.

1.11 (Related to the Don't Let This Happen to You on page 384) LaToya is buying corn chips and soda. She has 4 bags of corn chips and 5 bottles of soda in her shopping cart. The marginal utility of the fourth bag of corn chips is 10, and the marginal utility of the fifth bottle of soda is also 10. Is LaToya maximizing utility? Briefly explain.

1.12 If the price of pizza had risen in the Super Bowl example on pages 385–386, both the income effect and the substitution effect would have caused you to eat less pizza; this explains that normal goods must obey the law of demand. If pizza were an inferior good, then the income effect and the substitution effect would have caused you to eat more pizza. What is the explanation of this paradox?

10.2 Where Demand Curves Come From, pages 386–389

LEARNING OBJECTIVE: Use the concept of utility to explain the law of demand.

Summary

When the price of a good falls, the ratio of the marginal utility to price rises. This change leads consumers to buy more of that good. As a result, whenever the price of a product falls, the quantity demanded increases. We saw in Chapter 3, Section 3.1 that this relationship is known as the *law of demand*. The market demand curve can be constructed from the individual demand curves for all the consumers in the market.

Review Questions

2.1 Explain how a downward-sloping demand curve results from consumers adjusting their consumption choices to changes in price.

- How would you derive the market demand curve for a private good and a public good?
- What law ensures that demand curves are downward sloping? Does it always hold true?

Problems and Applications

- Considering only the income effect, if the price of an inferior good declines, would a consumer want to buy a larger quantity or a smaller quantity of the good? Does your answer mean that the demand curves for inferior goods should slope upward? Briefly explain.
- The chapter states that “when the price of an inferior good falls, the income effect and substitution effect work in opposite directions.” Explain what this statement means.
- Suppose the market for ice cream cones is made up of three consumers: Tiago, Terrell, and Tim. Use the information

in the following table to construct the market demand curve for ice cream cones. Show the information in a table and in a graph.

	Tiago	Terrell	Tim
Price	Quantity Demanded (cones per week)	Quantity Demanded (cones per week)	Quantity Demanded (cones per week)
\$1.75	2	1	0
1.50	4	3	2
1.25	6	4	3
1.00	7	6	4
0.75	9	7	5

- 2.7 Marty and Ann discussed the rule of equal marginal utility per dollar spent, a topic that was recently covered in the economics course they were both taking:

Marty: “When I use my calculator to divide the marginal utility of pizza by a price of zero, I don’t get an answer. This result must mean that if pizza were being sold for a price of zero, the quantity demanded would be infinite.”

Ann: “Marty, that can’t be true. No producer would be willing to ‘sell’ pizza, or any other product, for a zero price. Quantity demanded cannot be infinite, so zero prices cannot appear on demand curves and demand schedules.”

Assume that Marty and Ann ask you for advice. Which of their statements is correct?

- 2.8 Consider two goods: pillows and blankets. If a hotel increases the utility from pillows to blankets, then it increases the utility of pillows more than it decreases the utility of blankets. This means it moves dollars from pillows to blankets. How can you maximize the total utility using the marginal utility per dollar theory?
- 2.9 (Related to **Making the Connection on page 388**) In studying the consumption of very poor families in China, Robert Jensen and Nolan Miller found that in both Hunan and Gansu, “Giffen behavior is most likely to be found among a range of households that are poor (but not too poor or too rich).”

- a. What do Jensen and Miller mean by “Giffen behavior”?
- b. Why would the poorest of the poor be less likely than people with slightly higher incomes to exhibit this behavior?
- c. Why must a good make up a very large portion of consumers’ budgets to be a Giffen good?

- 2.10 According to an article in *The Economist*, since the financial crisis, the demand for oil tankers has boomed: a combination of weak spot prices and higher futures prices encouraged traders to hire tankers to store oil at sea and cash in on the price gap. This was driven by the assumption that supply and demand for crude will eventually rebalance. Bulk carriers, meanwhile, have been hit by massive over-capacity, as Chinese demand for such commodities reduced drastically. Do you think oil tankers are normal goods and bulk carriers are inferior goods or vice versa? Is your answer important for predicting how many oil tankers will be in the market as a result of a price increase in oil? What about bulk carriers, if the prices of ore and coal are still decreasing? Briefly explain.

- 2.11 According to an article in *The Economist*, citizens of the United States consider college to be the best investment in the country. However, this view is based on broad averages, which obscure the difference among the country’s 7,800 higher-education institutions. Students are not assigned to colleges randomly, which makes it difficult for economists to determine which schools are worth the cost. For example, are Harvard graduates successful because they went to the institution or would they have succeeded no matter where they studied? For the following questions, assume that no factor affects the demand for high quality educational services other than prices.

- a. If universities increased the prices of educational services, can we conclude that, for students, the service was a normal good?
- b. If universities decreased the prices of educational services, can we conclude that, for students, the educational service is an inferior good?

10.3 Social Influences on Decision Making, pages 389–395

LEARNING OBJECTIVE: Explain how social influences can affect consumption choices.

Summary

Social factors can have an effect on consumption. For example, the amount of utility people receive from consuming a good often depends on how many other people they know who also consume the good. There is a **network externality** in the consumption of a product if the usefulness of the product increases with the number of consumers who use it. There is evidence that people like to be treated fairly and that they usually attempt to treat others fairly, even if doing so makes them worse off

financially. This result has been demonstrated in laboratory experiments such as the ultimatum game. When firms set prices, they take into account consumers’ preference for fairness. For example, hardware stores often do not increase the price of snow shovels to take advantage of a temporary increase in demand following a snowstorm.

Behavioral Economics: Do People Make Their Choices Rationally? pages 395–400

LEARNING OBJECTIVE: Describe the behavioral economics approach to understanding decision making.

Summary

Behavioral economics is the study of situations in which people act in ways that are not economically rational. **Opportunity cost** is the highest-valued alternative that must be given up to engage in an activity. People would improve their decision making if they took into account nonmonetary opportunity costs. People sometimes ignore nonmonetary opportunity costs because of the **endowment effect**—the tendency of people to be unwilling to sell something they already own even if they are offered a price that is greater than the price they would be willing to pay to buy the good if they didn't already own it. People would also improve their decision making if they ignored *sunk costs*. A **sunk cost** is a cost that has already been paid and cannot be recovered. Finally, people would improve their decision making if they were more realistic

about their future behavior. Behavioral economics gives insights into consumer behavior that can guide business strategies.

In summer, with the purpose of selling his horses, John takes his carriage, drawn by two horses to a horse market in Missouri. A salesman at the market proposed to buy one of his horses for \$3,000. However, John refused this offer. Using behavioral economic concepts, explain the reason for John's refusal.
- 4.6 Richard Thaler, an economist at the University of Chicago, is the person who first used the term *endowment effect* to describe placing a higher value on something already owned than would be placed on the object if not currently owned. According to an article in the *Economist*:

Dr. Thaler, who recently had some expensive bottles of wine stolen, observes that he is “now confronted with precisely one of my own experiments: these are bottles I wasn't planning to sell and now I'm going to get a cheque from an insurance company and most of these bottles I will not buy. I'm a good enough economist to know there's a bit of an inconsistency there.”

Based on Thaler's statement, how do his stolen bottles of wine illustrate the endowment effect, and why does he make the statement: “I'm a good enough economist to know there's a bit of an inconsistency there”?

Are you being irrational if you keep the copy rather than sell it?
- 4.8 Someone who owns a townhouse wrote to a real estate advice columnist to ask whether he should sell his townhouse or wait and sell it in the future, when he hoped that prices would be higher. The columnist replied: “Ask yourself: Would you buy this townhouse today as an investment? Because every day you don't sell it, you're buying it.” Do you agree with the columnist? In what sense are you buying something if you don't sell it? Should the owner's decision about whether to sell depend on what price he originally paid for the townhouse?

- When Andrea was young, she was unrealistic about her future behavior. Therefore, she did not act rationally.
 - Andrea was not working when she was young. After she graduated from college and became employed, her income rose. We can conclude that for Andrea, chicken, meatballs, and other meat products are inferior goods.

Using Indifference Curves and Budget Lines to Understand Consumer Behavior

LEARNING OBJECTIVE: Use indifference curves and budget lines to understand consumer behavior.

Consumer Preferences

In this chapter, we analyzed consumer behavior using the assumption that satisfaction, or *utility*, is measurable in utils. Although this assumption made our analysis easier to understand, it is unrealistic. In this appendix, we use the more realistic assumption that consumers are able to *rank* different combinations of goods and services in terms of how much utility they provide. For example, a consumer is able to determine whether he or she prefers 2 slices of pizza and 1 can of Coke or 1 slice of pizza and 2 cans of Coke, even if the consumer is unsure exactly how much utility he or she would receive from consuming these goods. This approach has the advantage of allowing us to actually draw a map of a consumer's preferences.

To begin with, suppose that a consumer is presented with the following alternatives, or *consumption bundles*:

Consumption Bundle A	Consumption Bundle B
2 slices of pizza and 1 can of Coke	1 slice of pizza and 2 cans of Coke

We assume that the consumer will always be able to decide which of the following is true:

- The consumer prefers bundle A to bundle B.
- The consumer prefers bundle B to bundle A.
- The consumer is indifferent between bundle A and bundle B. That is, the consumer would be equally happy to receive either bundle, so we can say the consumer receives equal utility from the two bundles.

For consistency, we also assume that the consumer's preferences are *transitive*. For example, if a consumer prefers pepperoni pizza to mushroom pizza and prefers mushroom pizza to anchovy pizza, the consumer must prefer pepperoni pizza to anchovy pizza.

Indifference Curves

Given the assumptions in the preceding section, we can draw a map of a consumer's preferences by using indifference curves. An **indifference curve** shows combinations of consumption bundles that give the consumer the same utility. In reality, consumers choose among consumption bundles containing many goods and services, but to make the discussion easier to follow, we will assume that only two goods are involved. Nothing important would change if we expanded the discussion to include many goods instead of just two.

The table in Figure 10A.1 gives Dave's preferences for pizza and Coke. The graph plots the information from the table. Every possible combination of pizza and Coke will have an indifference curve passing through it, although in the figure we have shown only four of Dave's indifference curves. Dave is indifferent among all the consumption bundles that are on the same indifference curve. So, he is indifferent among bundles E, B, and F because they all lie on indifference curve I_3 . Even though Dave has 4 fewer cans of Coke with bundle B than with bundle E, the additional slice of pizza he has in bundle B results in his having the same amount of utility at both points.

Indifference curve A curve that shows the combinations of consumption bundles that give the consumer the same utility.

Consumption Bundle	Slices of Pizza	Cans of Coke
A	1	2
B	3	4
C	4	5
D	1	6
E	2	8
F	5	2

MyEconLab Animation

Figure 10A.1

Plotting Dave's Preferences for Pizza and Coke

Every possible combination of pizza and Coke will have an indifference curve passing through it, although in the graph we show just four of Dave's indifference curves. Dave is indifferent among all the consumption bundles that are on the same indifference curve. So, he is indifferent among bundles E, B, and F because they all lie on indifference curve I_3 . Moving to the upper right in the graph increases the quantities of both goods available for Dave to consume. Therefore, the further to the upper right the indifference curve is, the greater the utility Dave receives.

Even without looking at Dave's indifference curves, we know he will prefer consumption bundle D to consumption bundle A because in D he receives the same quantity of pizza as in A but 4 additional cans of Coke. But we need to know Dave's preferences, as shown by his indifference curves, to know how he will rank bundle B and bundle D . Bundle D contains more Coke but less pizza than bundle B , so Dave's ranking will depend on how much pizza he would be willing to give up to receive more Coke. The higher the indifference curve—that is, the further to the upper right on the graph—the greater the amounts of both goods that are available for Dave to consume and the greater his utility. In other words, Dave receives more utility from the consumption bundles on indifference curve I_2 than from the consumption bundles on indifference curve I_1 , more utility from the bundles on I_3 than from the bundles on I_2 , and so on.

MyEconLab Concept Check

The Slope of an Indifference Curve

Remember that the slope of a curve is the ratio of the change in the variable on the vertical axis to the change in the variable on the horizontal axis. Along an indifference curve, the slope tells us the rate at which the consumer is willing to trade off one product for another while keeping the consumer's utility constant. Economists call this rate the **marginal rate of substitution (MRS)**.

We expect that the MRS will change as we move down an indifference curve. In Figure 10A.1, at a point like E on indifference curve I_3 , Dave's indifference curve is relatively steep. As we move down the curve, it becomes less steep, until it becomes relatively flat at a point like F . This is the usual shape of indifference curves: They are bowed in, or convex. A consumption bundle like E contains a lot of Coke and not much pizza. We would expect that Dave could give up a significant quantity of Coke for a smaller quantity of additional pizza and still have the same level of utility. Therefore, the MRS will be high. As we move down the indifference curve, Dave moves to bundles, like B and F , that have more pizza and less Coke. At those points, Dave is willing to trade less Coke for pizza, and the MRS declines.

MyEconLab Concept Check

Can Indifference Curves Ever Cross?

Remember that we assume that consumers have transitive preferences. That is, if Dave prefers consumption bundle X to consumption bundle Y and prefers consumption bundle Y to consumption bundle Z , he must prefer bundle X to bundle Z . If indifference curves cross, this assumption is violated. To understand why, look at Figure 10A.2, which shows two of Dave's indifference curves crossing.

Because bundle X and bundle Z are both on indifference curve I_1 , Dave must be indifferent between them. Similarly, because bundle X and bundle Y are on indifference curve I_2 , Dave must be indifferent between them. The assumption of transitivity means that Dave should also be indifferent between bundle Z and bundle Y . We know he won't be,

Marginal rate of substitution (MRS) The rate at which a consumer would be willing to trade off one good for another.

MyEconLab Animation

Figure 10A.2

Indifference Curves Cannot Cross

Because bundle X and bundle Z are both on indifference curve I_1 , Dave must be indifferent between them. Similarly, because bundle X and bundle Y are on indifference curve I_2 , Dave must be indifferent between them. The assumption of transitivity means that Dave should also be indifferent between bundle Z and bundle Y. We know he won't be, however, because bundle Y contains more pizza and more Coke than bundle Z. So, Dave will definitely prefer bundle Y to bundle Z, which violates the assumption of transitivity. Therefore, none of Dave's indifference curves can cross.

The Budget Constraint

Remember that a consumer's *budget constraint* is the amount of income he or she has available to spend on goods and services. Suppose that Dave has \$10 per week to spend on pizza and Coke. The table in Figure 10A.3 shows the combinations that he can afford

MyEconLab Animation

Figure 10A.3

Dave's Budget Constraint

Dave's budget constraint shows the combinations of slices of pizza and cans of Coke he can buy with \$10. The price of Coke is \$1 per can, so if he spends all of his \$10 on Coke, he can buy 10 cans (bundle G). The price of pizza is \$2 per slice, so if he spends all of his \$10 on pizza, he can buy 5 slices (bundle L). As he moves down his budget constraint from bundle G, he gives up 2 cans of Coke for every slice of pizza he buys. Any consumption bundles along the line or inside the line are affordable. Any bundles that lie outside the line are unaffordable.

Combinations of Pizza and Coke Dave Can Buy with \$10			
Consumption Bundle	Slices of Pizza	Cans of Coke	Total Spending
G	0	10	\$10.00
H	1	8	10.00
I	2	6	10.00
J	3	4	10.00
K	4	2	10.00
L	5	0	10.00

to buy if the price of pizza is \$2 per slice and the price of Coke is \$1 per can. As you can see, all the points lie on a straight line. This line represents Dave's budget constraint. The line intersects the vertical axis at the maximum number of cans of Coke Dave can afford to buy with \$10, which is consumption bundle G. The line intersects the horizontal axis at the maximum number of slices of pizza Dave can afford to buy with \$10, which is consumption bundle L. As he moves down his budget constraint from bundle G, he gives up 2 cans of Coke for every slice of pizza he buys.

Any consumption bundle along the line or inside the line is *affordable* for Dave because he has the income to buy those combinations of pizza and Coke. Any bundle that lies outside the line is *unaffordable* because those bundles cost more than the income Dave has available to spend.

The slope of the budget constraint is constant because the budget constraint is a straight line. The slope of the line equals the change in the number of cans of Coke divided by the change in the number of slices of pizza. In this case, moving down the budget constraint from one point to another point, the change in the number of cans of Coke equals -2 , and the change in the number of slices of pizza equals 1 , so the slope equals $-2/1$, or -2 . Notice that with the price of pizza equal to \$2 per slice and the price of Coke equal to \$1 per can, the slope of the budget constraint is equal to the ratio of the price of pizza to the price of Coke (multiplied by -1). In fact, this result will always hold: *The slope of the budget constraint is equal to the ratio of the price of the good on the horizontal axis divided by the price of the good on the vertical axis multiplied by -1 .*

Choosing the Optimal Consumption of Pizza and Coke

Dave would like to be on the highest possible indifference curve because higher indifference curves represent more pizza and more Coke. But Dave can only buy the bundles that lie on or inside his budget constraint. In other words, *to maximize utility, a consumer needs to be on the highest indifference curve, given his budget constraint.*

Figure 10A.4 plots the consumption bundles from Figure 10A.1 along with the budget constraint from Figure 10A.3. The figure also shows the indifference curves that pass through each consumption bundle. In Figure 10A.4, the highest indifference curve

Finding Optimal Consumption

Dave would like to be on the highest possible indifference curve, but he cannot reach indifference curves such as I_4 that are outside his budget constraint. Dave's optimal combination of slices of pizza and cans of Coke is at point B, where his budget constraint just touches—or is *tangent* to—the highest indifference curve he can reach. At point B, he buys 3 slices of pizza and 4 cans of Coke.

shown is I_4 . Unfortunately, Dave lacks the income to purchase consumption bundles—such as C —that lie on I_4 . He has the income to purchase bundles such as A and D , but he can do better. If he consumes bundle B , he will be on the highest indifference curve he can reach, given his budget constraint of \$10. The resulting combination of 3 slices of pizza and 4 cans of Coke represents Dave's optimal consumption of pizza and Coke, given his preferences and his budget constraint. Notice that at point B , Dave's budget constraint just touches—or is *tangent* to— I_3 . In fact, bundle B is the only bundle on I_3 that Dave is able to purchase for \$10.

Dell Determines the Optimal Mix of Products

Consumers have different preferences, which helps explain why many firms offer products with a variety of characteristics. For example, Dell sells laptop computers with different screen sizes, processor speeds, hard drive sizes, graphics cards, and so on. We can use the model of consumer choice to analyze a simplified version of the situation Dell faces in deciding which features to offer consumers.

Assume that consumers have \$500 each to spend on a Dell laptop and that they are concerned with only two laptop characteristics: screen size and processor speed. Because larger screens and faster processors increase Dell's cost of producing laptops, consumers face a trade-off: The larger the screen, the slower the processor speed. Consumers in panel (a) of the figure prefer screen size to processor speed. For this group, the point of tangency between a typical consumer's indifference curve and the budget constraint shows an optimal choice of a 17-inch screen and a 2.0-gigahertz processor. Consumers in panel (b) prefer processor speed to screen size. For this group, the point of tangency between a typical consumer's indifference curve and the budget constraint shows an optimal choice of a 13-inch screen and 3.4-gigahertz processor.

Companies such as Dell use surveys and other means to gather information about consumer preferences. With knowledge of consumers' preferences and data on the costs of producing different laptop components, Dell can determine the mix of components to offer consumers.

Figure 10A.5

How a Price Decrease Affects the Budget Constraint

A fall in the price of pizza from \$2 per slice to \$1 per slice increases the maximum number of slices Dave can buy with \$10 from 5 to 10. The budget constraint rotates outward from point A to point B to show the effect of the price decrease.

Deriving the Demand Curve

Suppose the price of pizza falls from \$2 per slice to \$1 per slice. How will this change affect Dave's decision about which combination of pizza and Coke is optimal? First, notice what happens to Dave's budget constraint when the price of pizza falls. As Figure 10A.5 shows, when the price of pizza is \$2 per slice, the maximum number of slices Dave can buy is 5. After the price of pizza falls to \$1 per slice, Dave can buy a maximum of 10 slices. His budget constraint rotates outward from point A to point B to represent this. (Notice that the fall in the price of pizza does not affect the maximum number of cans of Coke Dave can buy with his \$10.)

When his budget constraint rotates outward, Dave is able to purchase consumption bundles that were previously unaffordable. Panel (a) of Figure 10A.6 shows that the combination of 3 slices of pizza and 4 cans of Coke was optimal when the price of pizza was \$2 per slice, but the combination of 7 slices of pizza and 3 cans of Coke is optimal when the price of pizza falls to \$1. The lower price of pizza causes Dave to consume more pizza and less Coke and to end up on a higher indifference curve.

The change in Dave's optimal consumption of pizza as the price changes explains why demand curves slope downward. Dave adjusted his consumption of pizza as follows:

Price of pizza = \$2 per slice → Quantity of pizza demanded = 3 slices

Price of pizza = \$1 per slice → Quantity of pizza demanded = 7 slices

In panel (b) of Figure 10A.6, we plot the two points of optimal consumption and draw a line to connect the points. This downward-sloping line is Dave's demand curve for pizza. We could find more points on the demand curve by changing the price of pizza and finding the new optimal number of slices of pizza Dave would demand.

Remember that according to the law of demand, demand curves always slope downward. We have just shown that the law of demand results from the optimal adjustment by consumers to changes in prices. A fall in the price of a good will rotate *outward* the budget constraint and make it possible for a consumer to reach higher indifference curves. As a result, the consumer will increase the quantity of the good demanded. An increase in price will rotate *inward* the budget constraint and force the consumer to a lower indifference curve. As a result, the consumer will decrease the quantity of the good demanded.

MyEconLab Animation

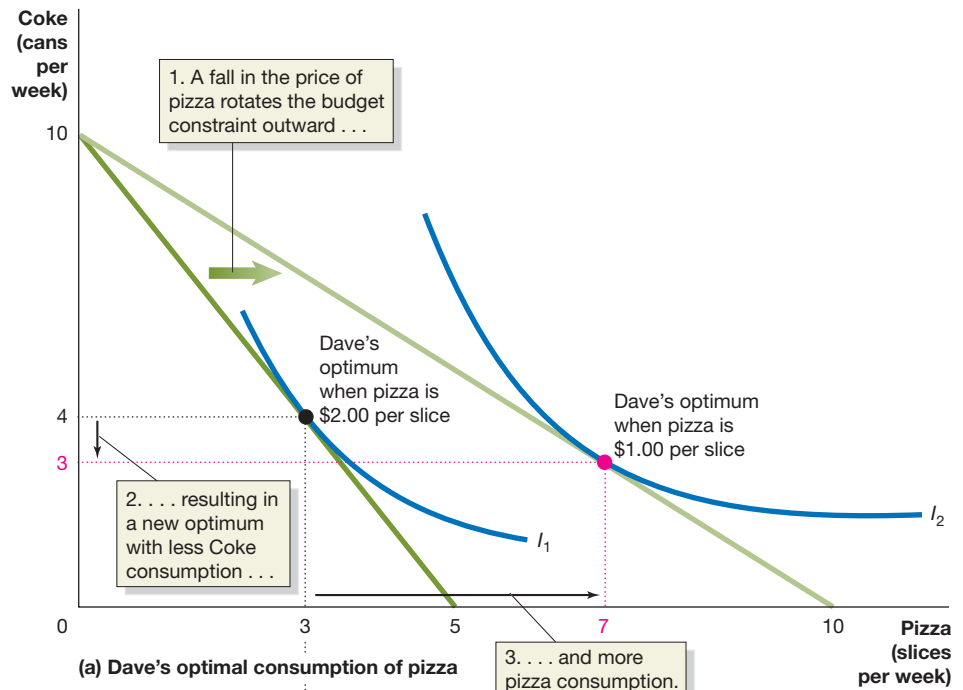

Figure 10A.6

How a Price Change Affects Optimal Consumption

In panel (a), a fall in the price of pizza results in Dave’s consuming less Coke and more pizza:

1. A fall in the price of pizza rotates the budget constraint outward because Dave can now buy more pizza with his \$10.
2. In the new optimum on indifference curve I_2 , Dave changes the quantities he consumes of both goods. His consumption of Coke falls from 4 cans to 3 cans.
3. In the new optimum, Dave’s consumption of pizza increases from 3 slices to 7 slices.

In panel (b), Dave responds optimally to the fall in the price of pizza from \$2 per slice to \$1 per slice by increasing the quantity of slices he consumes from 3 slices to 7 slices. When we graph this result, we have Dave’s demand curve for pizza.

Solved Problem 10A.1

MyEconLab Interactive Animation

When Does a Price Change Make a Consumer Better Off?

Dave has \$300 to spend each month on pizzas and downloads of movies. Pizzas and movie downloads have a price of \$10, and Dave is maximizing his utility by buying 20 pizzas and 10 movies. Suppose Dave still has \$300

to spend, but the price of movies rises to \$20, while the price of pizzas drops to \$5. Is Dave better or worse off than he was before the price change? Use a budget constraint–indifference curve graph to illustrate your answer.

Solving the Problem

Step 1: Review the chapter material. This problem concerns the effect of price changes on optimal consumption, so you may want to review the section “Deriving the Demand Curve,” which begins on page 413.

Step 2: Solve the problem by drawing the appropriate graph. We begin by drawing the budget constraint, indifference curve, and point of optimal consumption for the original prices:

Now draw a graph that shows the results of the price changes. Notice that in this problem, the prices of *both* goods change. You can determine the position of the new budget constraint by calculating the maximum quantity of pizzas and movies Dave can buy after the price changes. You should also note that after the price changes, Dave can still buy his original optimal consumption bundle—20 pizzas and 10 movies—by spending all his \$300, so his new budget constraint must pass through this point.

At the new prices, Dave can buy a maximum of 60 pizzas or 15 movies. Both his old and new budget constraints pass through the consumption bundle at point A. This consumption bundle is no longer optimal, however, because with the new prices, it is possible for him to reach an indifference curve that is higher than I_1 . We can draw in the new highest indifference curve he can reach— I_2 —and show the new optimal consumption bundle—point B.

Because Dave can now reach a higher indifference curve, we can conclude that he is better off as a result of the price change.

Your Turn: For more practice, do related problem 10A.10 on page 420 at the end of this appendix.

The Income Effect and the Substitution Effect of a Price Change

We saw in this chapter that a price change has these two effects on the quantity of a good consumed:

1. The *substitution effect* is the change in the quantity demanded of a good that results from a change in price making the good more or less expensive relative to other goods, holding constant the effect of the price change on consumer purchasing power.
2. The *income effect* is the change in the quantity demanded of a good that results from the effect of a change in price on consumer purchasing power, holding all other factors constant.

We can use indifference curves and budget constraints to analyze these two effects more precisely.

Figure 10A.7 illustrates the same situation as in Figure 10A.6: The price of pizza has fallen from \$2 per slice to \$1 per slice, and Dave's budget constraint has rotated outward. As before, Dave's optimal consumption of pizza increases from 3 slices per week (point A in Figure 10A.7) to 7 slices per week (point C). We can think of this movement from point A to point C as taking place in two steps: The movement from point A to point B represents the substitution effect, and the movement from point B to point C represents the income effect. To isolate the substitution effect, we have to hold constant the effect of the price change on Dave's income. We do this by changing the price of pizza relative to the price of Coke *but at the same time holding his utility constant by keeping Dave on the same indifference curve*. In Figure 10A.7, in moving from point A to point B, Dave remains on indifference curve I_1 . Point A is a point of tangency between I_1 and Dave's original budget constraint. Point B is a point of tangency between I_1 and a new, hypothetical budget constraint that has a slope equal to the new ratio of the price of pizza to the price of Coke. At point B, Dave has increased his consumption of pizza from 3 slices to 5 slices. Because we are still on indifference curve I_1 , we know that this increase is Dave's response only to the change in the relative price of pizza and, therefore, that the increase represents the substitution effect of the fall in the price of pizza.

At point B, Dave has not spent all his income. Remember that the fall in the price of pizza has increased Dave's purchasing power. In Figure 10A.7, we illustrate the additional pizza Dave consumes because of the income effect of increased purchasing

MyEconLab Animation

Figure 10A.7

Income and Substitution Effects of a Price Change

Following a decline in the price of pizza, Dave's optimal consumption of pizza increases from 3 slices per week (point A) to 7 slices per week (point C). We can think of this movement from point A to point C as taking place in two steps: The movement from point A to point B along indifference curve I_1 represents the substitution effect, and the movement from point B to point C represents the income effect. Dave increases his consumption of pizza from 3 slices per week to 5 slices per week because of the substitution effect of a fall in the price of pizza and from 5 slices per week to 7 slices per week because of the income effect.

MyEconLab Animation

Figure 10A.8

How a Change in Income Affects the Budget Constraint

When the income Dave has to spend on pizza and Coke increases from \$10 to \$20, his budget constraint shifts outward. With \$10, Dave could buy a maximum of 5 slices of pizza or 10 cans of Coke. With \$20, he can buy a maximum of 10 slices of pizza or 20 cans of Coke.

power by the movement from point *B* to point *C*. Notice that in moving from point *B* to point *C*, the price of pizza relative to the price of Coke is constant because the slope of the new budget constraint is the same as the slope of the hypothetical budget constraint that is tangent to I_1 at point *B*.

We can conclude that Dave increases his consumption of pizza from 3 slices per week to 5 slices per week because of the substitution effect of a fall in the price of pizza and from 5 slices per week to 7 slices per week because of the income effect. Recall from our discussion of income and substitution effects in this chapter that the income effect of a price decline causes consumers to buy more of a normal good and less of an inferior good. Because the income effect causes Dave to increase his consumption of pizza, pizza must be a normal good for him.

MyEconLab Concept Check

How a Change in Income Affects Optimal Consumption

Suppose that the price of pizza remains at \$2 per slice, but the income Dave has to spend on pizza and Coke increases from \$10 to \$20. Figure 10A.8 shows how this change affects his budget constraint. With an income of \$10, Dave could buy a maximum of 5 slices of pizza or 10 cans of Coke. With an income of \$20, he can buy 10 slices of pizza or 20 cans of Coke. The additional income allows Dave to increase his consumption of both pizza and Coke and to move to a higher indifference curve.

Figure 10A.9 shows Dave's new optimum. Dave is able to increase his consumption of pizza from 3 to 7 slices per week and his consumption of Coke from 4 to 6 cans per week.

MyEconLab Concept Check

The Slope of the Indifference Curve, the Slope of the Budget Line, and the Rule of Equal Marginal Utility per Dollar Spent

In this chapter, we saw that consumers maximize utility when they consume each good up to the point where the marginal utility per dollar spent is the same for every good. This condition seems different from the one we stated earlier in this appendix that to maximize utility, a consumer needs to be on the highest indifference curve, given his budget constraint. In fact, the two conditions are equivalent. To see this, begin by looking at Figure 10A.10, which again combines Dave's indifference curve and budget constraint. Remember that at the point of optimal consumption, the indifference curve and

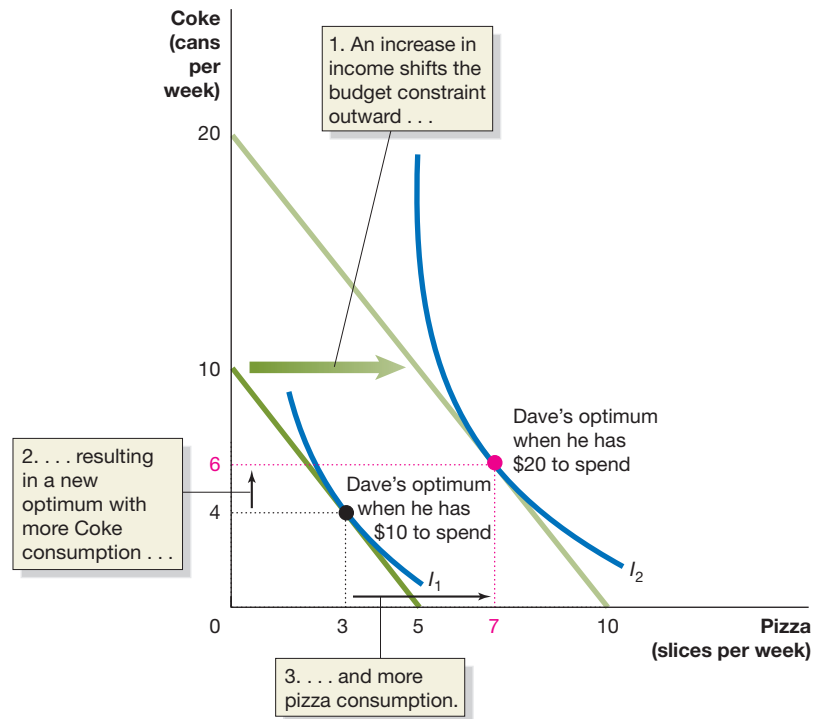

MyEconLab Animation

Figure 10A.9

How a Change in Income Affects Optimal Consumption

An increase in income leads Dave to consume more Coke and more pizza:

1. An increase in income shifts Dave's budget constraint outward because he can now buy more of both goods.
2. In the new optimum on indifference curve I_2 , Dave changes the quantities he consumes of both goods. His consumption of Coke increases from 4 to 6 cans.
3. In the new optimum, Dave's consumption of pizza increases from 3 to 7 slices.

the budget constraint are tangent, so they have the same slope. Therefore, *at the point of optimal consumption, the marginal rate of substitution (MRS) is equal to the ratio of the price of the product on the horizontal axis to the price of the product on the vertical axis.*

The slope of the indifference curve tells us the rate at which a consumer is *willing* to trade off one good for the other. The slope of the budget constraint tells us the rate at which a consumer is *able* to trade off one good for the other. Only at the point of optimal consumption is the rate at which a consumer is willing to trade off one good for the other equal to the rate at which the consumer can trade off one good for the other.

The Rule of Equal Marginal Utility per Dollar Spent Revisited

Recall from this chapter the *rule of equal marginal utility per dollar*, which states that to maximize utility, consumers should spend their income so that the last dollar spent on

MyEconLab Animation

Figure 10A.10

At the Optimum Point, the Slopes of the Indifference Curve and Budget Constraint Are the Same

At the point of optimal consumption, the marginal rate of substitution is equal to the ratio of the price of the product on the horizontal axis to the price of the product on the vertical axis.

each product gives them the same marginal utility. We can use our indifference curve and budget constraint analysis to see why this rule holds. When we move from one point on an indifference curve to another, we end up with more of one product and less of the other product but the same amount of utility. For example, as Dave moves down an indifference curve, he consumes less Coke and more pizza, but he has the same amount of utility.

Remember that marginal utility (MU) tells us how much additional utility a consumer gains (or loses) from consuming more (or less) of a good. So when Dave consumes less Coke by moving down an indifference curve, he loses utility equal to:

$$-\text{Change in the quantity of Coke} \times MU_{\text{Coke}}$$

but he consumes more pizza, so he gains utility equal to:

$$\text{Change in the quantity of Pizza} \times MU_{\text{Pizza}}$$

We know that the gain in utility from the additional pizza is equal to the loss from the smaller quantity of Coke because Dave's total utility remains the same along an indifference curve. Therefore, we can write:

$$-(\text{Change in the quantity of Coke} \times MU_{\text{Coke}}) = (\text{Change in the quantity of pizza} \times MU_{\text{Pizza}}).$$

If we rearrange terms, we have:

$$\frac{-\text{Change in the quantity of Coke}}{\text{Change in the quantity of Pizza}} = \frac{MU_{\text{Pizza}}}{MU_{\text{Coke}}}.$$

Because the expression:

$$\frac{-\text{Change in the quantity of Coke}}{\text{Change in the quantity of Pizza}}$$

is the slope of the indifference curve, it is equal to the MRS (multiplied by -1). So, we can write:

$$\frac{-\text{Change in the quantity of Coke}}{\text{Change in the quantity of Pizza}} = MRS = \frac{MU_{\text{Pizza}}}{MU_{\text{Coke}}}.$$

The slope of Dave's budget constraint equals the price of pizza divided by the price of Coke (multiplied by -1). We saw earlier in this appendix that at the point of optimal consumption, the MRS equals the ratio of the prices of the two goods. Therefore:

$$\frac{MU_{\text{Pizza}}}{MU_{\text{Coke}}} = \frac{P_{\text{Pizza}}}{P_{\text{Coke}}}.$$

We can rewrite this to show that at the point of optimal consumption:

$$\frac{MU_{\text{Pizza}}}{P_{\text{Pizza}}} = \frac{MU_{\text{Coke}}}{P_{\text{Coke}}}.$$

This last expression is the rule of equal marginal utility per dollar that we first developed in this chapter. So we have shown how this rule follows from the indifference curve and budget constraint approach to analyzing consumer choice. [MyEconLab](#) [Concept Check](#)

Will the Cost of MOOCs Revolutionize Higher Education?

For hundreds of years, college education has typically taken place in lecture halls where instructors and students interact. A large part of the total cost of supplying college education is the expense of constructing and maintaining buildings and paying the salaries of instructors and administrators. Economists refer to these costs as *fixed costs* because they remain the same regardless of the number of students enrolled. The *marginal cost* of higher education, the cost of instructing one additional student, is very low as long as there are empty seats in classrooms. But once classrooms are full, the marginal cost rises significantly because a school would need to build more classrooms and hire more instructors.

New technology has started changing colleges' costs. For example, some colleges now offer massive open online courses (MOOCs). The fixed cost of an online course is relatively high because instructors must develop new syllabi, exams, and teaching notes, as well as determine when and how to interact with their students. But after the courses are placed online, the cost of providing instruction to an additional student is close to zero because instruction is not limited by the size of a classroom. Because the marginal cost is low, after the

fixed costs are covered, colleges can earn substantial revenues from MOOCs, even if they charge students low prices for these courses. In 2015, Arizona State announced that it would offer all its freshman year courses as MOOCs. Students will pay \$200 per credit but will be charged only after they have passed a course.

Early results for MOOCs have been mixed. Although some students do well in online courses, dropout rates tend to be higher than for traditional courses. In MOOCs with large enrollments, instructors cannot interact with individual students. And not all instructors are comfortable with the new technology. A major challenge that universities need to meet is determining how to evaluate student learning when traditional testing methods can't be used. But the cost advantages of online instruction suggest that it will not be a passing fad.

In this chapter, we will analyze the types of costs involved in the production of a good or service and see how those costs affect how firms operate.

Economics in Your Life

Using Cost Concepts in Your Online Business

Suppose you are considering starting a Web site to sell iPhone cases online. You locate a Taiwanese manufacturer who will sell you the cases for \$10 each. Your friend José already is running such a site, and you plan to buy the same computers and software that José uses. Like José, you intend to rent a small building in an industrial park where you can have an office and storage space for your inventory. You plan to sell the cases for \$15. You find out that José is selling more cases per month than you expect to sell and that he is selling them for only \$13. You wonder how José makes a profit at the lower price. As José sells more cases per month, will his firm's costs be lower than your firm's costs? As you read the chapter, see if you can answer this question. You can check your answers against those we provide on **page 442** at the end of this chapter.

In Chapter 10, we looked behind the demand curve to better understand consumer decision making. In this chapter, we look behind the supply curve to better understand firm decision making. Earlier chapters showed that supply curves are upward sloping because marginal cost increases as firms increase the quantity of a good that they supply. In this chapter, we look more closely at why this is true. In the appendix to this chapter, we extend the analysis by using isoquants and isocost lines to understand the relationship between production and costs. Once we have a good understanding of production and cost, we can proceed in the following chapters to understand how firms decide what level of output to produce and what price to charge.

11.1 Technology: An Economic Definition

LEARNING OBJECTIVE: Define technology and give examples of technological change.

Technology The processes a firm uses to turn inputs into outputs of goods and services.

Technological change A change in the ability of a firm to produce a given level of output with a given quantity of inputs.

The basic activity of a firm is to use *inputs*, such as workers, machines, and natural resources, to produce *outputs* of goods and services. A pizza parlor, for example, uses inputs such as pizza dough, pizza sauce, cooks, and ovens to produce pizza. A firm's **technology** is the processes it uses to turn inputs into outputs of goods and services. Notice that this economic definition of technology is broader than the everyday definition. When we use the word *technology* in everyday language, we usually refer only to the development of new products. In the economic sense, a firm's technology depends on many factors, such as the skills of its managers, the training of its workers, and the speed and efficiency of its machinery and equipment. A pizza parlor's technology of pizza production, for example, includes not only the capacity of its pizza ovens and how quickly they bake the pizza but also how quickly the cooks can prepare the pizza for baking and how well the firm's manager motivates the workers and arranges the facilities to allow the cooks to quickly prepare the pizzas and get them in the ovens.

Whenever a firm experiences positive **technological change**, it is able to produce more output using the same inputs or the same output using fewer inputs. Positive technological change can come from many sources. A firm's managers may rearrange the factory floor or the layout of a retail store in order to increase production and sales. The firm's workers may go through a training program. The firm may install faster or more reliable machinery or equipment. It is also possible for a firm to experience negative technological change. If a firm, for example, hires less-skilled workers or if a hurricane damages its facilities, the quantity of output it can produce from a given quantity of inputs may decline.

UPS Uses Technology to Deal with a Surge in Holiday Packages

Christmas 2013 was not the season of joy at United Parcel Services (UPS). For decades, most of the company's business was shipping packages from one company to another. But with the rise of e-commerce sites such as Amazon starting in the late 1990s, the volume of packages being shipped to homes has greatly increased. Most shipments to homes consist of a single package, which makes delivery more costly than to businesses, where each shipment typically consists of multiple packages. During the holiday season, competition among Internet sellers, including Amazon, Walmart, and Target, has led them to guarantee deliveries by Christmas Eve, even on orders received as late as December 23. Although UPS—like its rival, FedEx—promised the sellers that it would be able to make the deliveries, in fact it failed to deliver millions of packages until Christmas morning or later. Parents had some explaining to do to their disappointed children ... and UPS managers had some explaining to do to Amazon and other Internet sellers.

To ensure that they met their commitments during the next holiday season, UPS managers could have hired more workers and purchased more airplanes. Although UPS

After struggling with a high volume of packages, UPS adopted new technology to deliver more packages with the same number of workers and planes.

does temporarily increase its hiring each December, doing so raises its costs. If the company bought more planes, they would sit unused during most of the year because fewer than half as many packages are delivered in other months as are delivered in December. UPS delivers more than 30 million packages on December 22 alone. Instead of continually increasing the number of workers and planes, UPS decided to use technology to allow it to deliver more packages with the same number of workers and planes.

Some of the new technology took the form of new equipment. Previously, employees in UPS sorting facilities needed to memorize more than 100 zip codes in order to know which chute to send a package down on its way to being deposited in a truck or plane. The new equipment scans a package and instantly tells the worker in which color-coded chute to place the package. This equipment allows UPS workers to process 15 percent more packages per day.

Other changes at UPS involved no new equipment but were instead improvements in the way packages were routed. The firm started using more detailed maps to plan the routes for packages. As a result, the typical delivery driver could travel fewer miles per day while delivering more packages. UPS also began taking better account of weather forecasts to avoid delays in flying packages. These improvements in handling packages meet the economic definition of positive technological change because they allow the firm to produce a larger output—more packages delivered—with the same amount of inputs—workers, planes, and other equipment.

Harnessing technological change can allow firms to reduce costs and better compete against other firms in their industry. In this case, UPS is using technology to make profitable the large volume of e-commerce packages the company delivers to homes.

11.2 The Short Run and the Long Run in Economics

LEARNING OBJECTIVE: Distinguish between the economic short run and the economic long run.

When firms analyze the relationship between their level of production and their costs, they separate the time period involved into the short run and the long run. In the **short run**, at least one of the firm’s inputs is fixed. In particular, in the short run, the firm’s technology and the size of its physical plant—its factory, store, or office—are both fixed, while the number of workers the firm hires is variable. In the **long run**, the firm is able to vary all its inputs and can adopt new technology and increase or decrease the size of its physical plant.

The actual length of calendar time before the short run becomes the long run differs from firm to firm. A pizza parlor may have a short run of just a few weeks before it is able to increase its physical plant by adding another pizza oven and some tables and chairs. General Motors, in contrast, may have a short run of a year or more before it can increase the capacity of one of its automobile assembly plants by installing new equipment.

The Difference between Fixed Costs and Variable Costs

Total cost is the cost of all the inputs a firm uses in production. We have just seen that in the short run, some inputs are fixed and others are variable. The costs of the fixed inputs are called *fixed costs*, and the costs of the variable inputs are called *variable costs*. We can also think of **variable costs** as the costs that change as output changes. Similarly, **fixed costs** are costs that remain constant as output changes. A typical firm’s variable costs include its labor costs, raw material costs, and costs of electricity and other utilities. Typical fixed costs include lease payments for factory or retail space, payments for

Fixed Costs in the Publishing Industry

An editor at Cambridge University Press gives the following estimates of the annual fixed cost for a medium-size academic book publisher:

Cost	Amount
Salaries and benefits	\$625,000
Rent	75,000
Utilities	20,000
Supplies	6,000
Postage	5,000
Travel	9,000
Subscriptions, etc.	5,000
Miscellaneous	5,000
Total	\$750,000

Academic book publishers hire editors, designers, and production and marketing managers who help prepare books for publication. Because these employees work on several books simultaneously, the number of people the company hires does not go up and down with the quantity of books the company publishes during any particular year. Publishing companies therefore consider the salaries and benefits of people in these job categories to be fixed costs.

In contrast, for a company that *prints* books, the quantity of workers varies with the quantity of books printed. The wages and benefits of the workers operating the printing presses, for example, would be a variable cost.

The other costs listed in the table are typical of fixed costs at many firms.

Opportunity cost The highest-valued alternative that must be given up to engage in an activity.

Explicit cost A cost that involves spending money.

Implicit cost A nonmonetary opportunity cost.

Implicit Costs versus Explicit Costs

Remember that economists always measure cost as **opportunity cost**, which is the highest-valued alternative that must be given up to engage in an activity. As we saw in Chapter 8, costs are either *explicit* or *implicit*. When a firm spends money, it incurs an **explicit cost**. When a firm experiences a nonmonetary opportunity cost, it incurs an **implicit cost**.

For example, suppose that Jill Johnson owns a pizza restaurant. Her explicit costs include the wages she pays her workers and the payments she makes for rent and electricity. But some of Jill's most important costs are implicit. Before opening her own restaurant, Jill earned a salary of \$30,000 per year managing a restaurant for someone else. To start her restaurant, Jill quit her job, withdrew \$50,000 from her bank account—where it earned her interest of \$3,000 per year—and used the funds to equip her restaurant with tables, chairs, a cash register, and other equipment. To open her own business, Jill had to give up the \$30,000 salary and the \$3,000 in interest. This \$33,000 is an implicit cost because it does not represent payments that Jill has to make. Nevertheless, giving up this \$33,000 per year is a real cost to Jill.

Jill's Costs	Amount
Pizza dough, tomato sauce, and other ingredients	\$20,000
Wages	48,000
Interest payments on loan to buy pizza ovens	10,000
Electricity	6,000
Lease payment for store	24,000
Forgone salary	30,000
Forgone interest	3,000
Economic depreciation	10,000
Total	\$151,000

Table 11.1
Jill Johnson's Costs per Year

In addition, during the course of the year, the \$50,000 worth of tables, chairs, and other physical capital in Jill's store will lose some of its value partly due to wear and tear and partly due to better furniture, cash registers, and so forth, becoming available. *Economic depreciation* is the difference between what Jill paid for her capital at the beginning of the year and what she would receive if she sold the capital at the end of the year. If Jill could sell the capital for \$40,000 at the end of the year, the \$10,000 in economic depreciation represents another implicit cost. (Note that the whole \$50,000 she spent on the capital is not a cost because she still has the equipment at the end of the year, although it is now worth only \$40,000.)

Table 11.1 lists Jill's costs. The entries in red are explicit costs, and the entries in blue are implicit costs. The rules of accounting generally require that only explicit costs be used for purposes of keeping the company's financial records and for paying taxes (see Chapter 8). Therefore, explicit costs are sometimes called *accounting costs*. *Economic costs* include both accounting costs and implicit costs. MyEconLab Concept Check

The Production Function

Let's look at the relationship in the short run between Jill Johnson's level of production and her costs. We can simplify the situation in Table 11.1 by assuming that Jill uses only labor—workers—and one type of capital—pizza ovens—to produce a single good: pizzas. Many firms use more than two inputs and produce more than one good, but it is easier to understand the relationship between output and cost by focusing on the case of a firm using only two inputs and producing only one good. In the short run, Jill doesn't have time to build a larger restaurant, install additional pizza ovens, or redesign the layout of her restaurant. So, in the short run, she can increase or decrease the quantity of pizzas she produces only by increasing or decreasing the number of workers she employs.

The first three columns of Table 11.2 show the relationship between the quantity of workers and ovens Jill uses per week and the quantity of pizzas she can produce.

Quantity of Workers	Quantity of Pizza Ovens	Quantity of Pizzas per Week	Cost of Pizza Ovens (Fixed Cost)	Cost of Workers (Variable Cost)	Total Cost of Pizzas per Week	Cost per Pizza (Average Total Cost)

Production function The relationship between the inputs employed by a firm and the maximum output it can produce with those inputs.

The relationship between the inputs employed by a firm and the maximum output it can produce with those inputs is called the firm's **production function**. Because a firm's technology is the processes it uses to turn inputs into output, the production function represents the firm's technology. The first three columns of Table 11.2 show Jill's *short-run* production function because we are assuming that the time period is too short for Jill to increase or decrease the quantity of ovens she is using. MyEconLab Concept Check

A First Look at the Relationship between Production and Cost

Table 11.2 shows Jill Johnson's costs. We can determine the total cost of producing a given quantity of pizzas if we know how many workers and ovens are required to produce that quantity and how much Jill has to pay for those workers and ovens. Suppose Jill has taken out a bank loan to buy two pizza ovens. The cost of the loan is \$800 per week. Therefore, her fixed costs are \$800 per week. If Jill pays \$650 per week to each worker, her variable costs depend on how many workers she hires. In the short run, Jill can increase the quantity of pizzas she produces only by hiring more workers. Table 11.2 shows that if she hires 1 worker, she produces 200 pizzas during the week; if she hires 2 workers, she produces 450 pizzas; and so on. For a particular week, Jill's total cost of producing pizzas is equal to the \$800 she pays on the loan for the ovens plus the amount she pays to hire workers. If Jill decides to hire 4 workers and produce 600 pizzas, her total cost is \$3,400: \$800 to lease the ovens and \$2,600 to hire the workers. Her cost per pizza is equal to her total cost of producing pizzas divided by the quantity of pizzas produced. If she produces 600 pizzas at a total cost of \$3,400, her cost per pizza, or *average total cost*, is $\$3,400/600 = \5.67 . A firm's **average total cost** is always equal to its total cost divided by the quantity of output produced.

Average total cost Total cost divided by the quantity of output produced.

total cost. Notice in panel (b) that Jill's average cost curve has a roughly U shape. As production increases from low levels, average total cost falls. Average total cost then becomes fairly flat, before rising at higher levels of production. To understand why average total cost curve has this U shape, we first need to look more closely at the technology of producing pizzas, as shown by the production function for Jill's restaurant. Then we need to look at how this technology determines the relationship between production and cost.

11.3 The Marginal Product of Labor and the Average Product of Labor

LEARNING OBJECTIVE: Understand the relationship between the marginal product of labor and the average product of labor.

To better understand the choices Jill faces, given the technology available to her, think first about what happens if she hires only one worker. That one worker will have to perform several different activities, including taking orders from customers, baking the pizzas, bringing the pizzas to the customers' tables, and ringing up sales on the cash register. If Jill hires two workers, some of these activities can be divided up: One worker could take the orders and ring up the sales, and one worker could bake the pizzas. With such a division of tasks, Jill will find that hiring two workers actually allows her to produce more than twice as many pizzas as she could produce with just one worker.

The additional output a firm produces as a result of hiring one more worker is called the **marginal product of labor**. We can calculate the marginal product of labor by determining how much total output increases as each additional worker is hired, which we do for Jill's restaurant in Table 11.3.

When Jill hires only one worker, she increases output from 0 pizzas to 200 pizzas per week. So, the marginal product of labor for the first worker is 200 pizzas. When she hires two workers, she produces 450 pizzas per week. Hiring the second worker increases her output by 250 pizzas per week. For the second worker, the marginal product of labor rises to 250 pizzas. This increase in marginal product results from the *division of labor* and from *specialization*. By dividing the tasks to be performed—the division of labor—Jill reduces the time workers lose moving from one activity to the next. She also allows them to become more specialized at their tasks. For example, a worker who concentrates on baking pizzas will become skilled at doing so quickly and efficiently.

The Law of Diminishing Returns

In the short run, the quantity of pizza ovens Jill leases is fixed, so as she hires more workers, the marginal product of labor eventually begins to decline. At some point, Jill uses up all the gains from the division of labor and from specialization and starts to experience the effects of the **law of diminishing returns**. This law states that adding more of a variable input, such as labor, to the same amount of a fixed input, such as capital, will eventually cause the marginal product of the variable input to decline. For Jill, the marginal product of labor begins to decline when she hires the third worker.

Marginal product of labor The additional output a firm produces as a result of hiring one more worker.

Law of diminishing returns The principle that, at some point, adding more of a variable input, such as labor, to the same amount of a fixed input, such as capital, will cause the marginal product of the variable input to decline.

Quantity of Workers	Quantity of Pizza Ovens	Quantity of Pizzas	Marginal Product of Labor
0	2	0	—
1	2	200	200
2	2	450	250
3	2	550	100
4	2	600	50
5	2	625	25
6	2	640	15

Table 11.3

The Marginal Product of Labor at Jill Johnson's Restaurant

Hiring three workers raises the quantity of pizzas she produces from 450 per week to 550. But the increase in the quantity of pizzas—100—is less than the increase when she hired the second worker—250—so the marginal product of labor has declined.

If Jill kept adding more and more workers to the same quantity of pizza ovens, workers would eventually begin to get in each other's way, and the marginal product of labor would actually become negative. When the marginal product is negative, the level of total output declines. No firm would actually hire so many workers as to experience a negative marginal product of labor and falling total output. **MyEconLab** **Concept Check**

Graphing Production

Panel (a) in Figure 11.2 graphs the relationship between the quantity of workers Jill hires and her total output of pizzas, using the numbers from Table 11.3. Panel (b) graphs the marginal product of labor. In panel (a), output increases as more workers are hired, but

MyEconLab Animation

Figure 11.2 Total Output and the Marginal Product of Labor

In panel (a), output increases as more workers are hired, but the increase in output does not occur at a constant rate. Because of specialization and the division of labor, output at first increases at an increasing rate, with each additional worker hired causing production to increase by a *greater* amount than did the hiring of the previous worker. When the point of diminishing returns is reached, production increases at a decreasing rate. Each

additional worker Jill hires after the second worker causes production to increase by a *smaller* amount than did the hiring of the previous worker. In panel (b), the *marginal product of labor* is the additional output produced as a result of hiring one more worker. The marginal product of labor rises initially because of the effects of specialization and division of labor, and then it falls because of the effects of diminishing returns.

the increase in output does not occur at a constant rate. Because of specialization and the division of labor, output at first increases at an increasing rate, with each additional worker hired causing production to increase by a *larger* amount than did the hiring of the previous worker. But after the second worker has been hired, hiring more workers while keeping the quantity of ovens constant results in diminishing returns. When the point of diminishing returns is reached, production increases at a decreasing rate. Each additional worker Jill hires after the second worker causes production to increase by a *smaller* amount than did the hiring of the previous worker. In panel (b), the marginal product of labor curve rises initially because of the effects of specialization and the division of labor, and then it falls because of the effects of diminishing returns. Adam Smith's Famous Account of the Division of Labor in a Pin Factory

The Wealth of Nations, written in Scotland by Adam Smith in 1776, is the first book to have discussed some of the key ideas of economics. Smith considered the concept of the division of labor important enough to discuss in the first chapter of the book. He illustrated the concept by using an example of a pin factory. The following is an excerpt from his account of how pin making was divided into a series of tasks:

One man draws out the wire, another straightens it, a third cuts it, a fourth points it, a fifth grinds it at the top for receiving the head; to make the head requires two or three distinct operations; to put it on is a . . . [distinct operation], to whiten the pins is another; it is even a trade by itself to put them into the paper; and the important business of making a pin is, in this manner, divided into eighteen distinct operations.

Because the labor of pin making was divided up in this way, an average worker was able to produce about 4,800 pins per day. Smith estimated that a single worker using the pin-making machinery by himself would make only about 20 pins per day. This lesson from 240 years ago, showing the tremendous gains from the division of labor and specialization, remains relevant to most business situations today.

The Relationship between Marginal Product and Average Product

The marginal product of labor tells us how much total output changes as the quantity of workers hired changes. We can also calculate the average quantity of pizzas workers produce. The **average product of labor** is the total output produced by a firm divided by the quantity of workers. For example, using the numbers in Table 11.3, if Jill hires 4 workers to produce 600 pizzas, the average product of labor is $600/4 = 150$.

We can state the relationship between the marginal and average products of labor this way: *The average product of labor is the average of the marginal products of labor.* For example, the numbers from Table 11.3 show that the marginal product of the first worker Jill hires is 200, the marginal product of the second worker is 250, and the marginal product of the third worker is 100. Therefore, the average product of labor for three workers is 183.3:

$$183.3 = (200 + 250 + 100) / 3$$

Average product of labor for three workers	Marginal product of labor of first worker	Marginal product of labor of second worker	Marginal product of labor of third worker
--	---	--	---

Average product of labor The total output produced by a firm divided by the quantity of workers.

By taking the average of the marginal products of the first three workers, we have the average product of the three workers.

Whenever the marginal product of labor is greater than the average product of labor, the average product of labor must be increasing. This statement is true for the same reason that a person 6 feet, 2 inches tall entering a room where the average height is 5 feet, 9 inches raises the average height of people in the room. Whenever the marginal product of labor is less than the average product of labor, the average product of labor must be decreasing. The marginal product of labor equals the average product of labor at the quantity of workers for which the average product of labor is at its maximum. MyEconLab Concept Check

An Example of Marginal and Average Values: College Grades

The relationship between the marginal product of labor and the average product of labor is the same as the relationship between the marginal and average values of any variable. To see this point more clearly, think about the familiar relationship between a student's grade point average (GPA) in one semester and his overall, or cumulative, GPA. The table in Figure 11.3 shows Paul's college grades for each semester, beginning

MyEconLab Animation

Figure 11.3

Marginal and Average GPAs

The relationship between marginal and average values for a variable can be illustrated using GPAs. We can calculate the GPA Paul earns in a particular semester (his "marginal GPA"), and we can calculate his cumulative GPA for all the semesters he has completed so far (his "average GPA"). Paul's GPA is only 1.50 in the fall semester of his first year. In each following semester through the fall of his junior year, his GPA for the semester increases—raising his cumulative GPA. In Paul's junior year, even though his semester GPA declines from fall to spring, his cumulative GPA rises. Only in the fall of his senior year, when his semester GPA drops below his cumulative GPA, does his cumulative GPA decline.

	Semester GPA (marginal GPA)	Cumulative GPA (average GPA)

Fall	1.50	1.50
Spring	2.00	1.75
<i>Sophomore year</i>		
Fall	2.20	1.90
Spring	3.00	2.18
<i>Junior year</i>		
Fall	3.20	2.38
Spring	3.00	2.48
<i>Senior year</i>		
Fall	2.40	2.47
Spring	2.00	2.41

Average GPA continues to rise, although marginal GPA falls.

With the marginal GPA below the average, the average GPA falls.

with fall of his first year. The graph in Figure 11.3 plots the grades from the table. Just as each additional worker hired adds to a firm's total production, each additional semester adds to Paul's total grade points. We can calculate what hiring each individual worker adds to total production (marginal product), and we can calculate the average production of the workers hired so far (average product).

Similarly, we can calculate the GPA Paul earns in a particular semester (his "marginal GPA"), and we can calculate his cumulative GPA for all the semesters he has completed so far (his "average GPA"). As the table shows, Paul gets off to a weak start in the fall semester of his first year, earning only a 1.50 GPA. In each subsequent semester through the fall of his junior year, his GPA for the semester increases from the previous semester—raising his cumulative GPA. As the graph shows, however, his cumulative GPA does not increase as rapidly as his semester-by-semester GPA because his cumulative GPA is held back by the low GPAs of his first few semesters. Notice that in Paul's junior year, even though his semester GPA declines from fall to spring, his cumulative GPA rises. Only in the fall of his senior year, when his semester GPA drops below his cumulative GPA, does his cumulative GPA decline.

11.4 The Relationship between Short-Run Production and Short-Run Cost

LEARNING OBJECTIVE: Explain and illustrate the relationship between marginal cost and average total cost.

We have seen that technology determines the values of the marginal product of labor and the average product of labor. In turn, the marginal and average products of labor affect the firm's costs. Keep in mind that the relationships we are discussing are *short-run* relationships: We are assuming that the time period is too short for the firm to change its technology or the size of its physical plant.

The average total cost curve in panel (b) of Figure 11.1 on page 428 for Jill Johnson's restaurant has a U shape. As we will soon see, the U shape of the average total cost curve is determined by the shape of the curve that shows the relationship between *marginal cost* and the level of production.

Marginal Cost

One of the key ideas in economics is that optimal decisions are made at the margin (see Chapter 1). Consumers, firms, and government officials usually make decisions about doing a little more or a little less. As Jill Johnson considers whether to hire additional workers to produce additional pizzas, she needs to consider how much she will add to her total cost by producing the additional pizzas. **Marginal cost** is the change in a firm's total cost from producing one more unit of a good or service. We can calculate marginal cost for a particular increase in output by dividing the change in total cost by the change in output. We can express this idea mathematically (remember that the Greek letter delta, Δ , means, "change in"):

$$MC = \frac{\Delta TC}{\Delta Q}$$

In the table in Figure 11.4, we use this equation to calculate Jill's marginal cost of producing pizzas. The other values in the table are from Table 11.2 and Table 11.3.

Marginal cost The change in a firm's total cost from producing one more unit of a good or service.

MyEconLab [Concept Check](#)

Why Are the Marginal and Average Cost Curves U Shaped?

Notice in the graph in Figure 11.4 that Jill's marginal cost of producing pizzas declines at first and then increases, giving the marginal cost curve a U shape. The table in Figure 11.4 also shows the marginal product of labor. This table helps us understand the important relationship between the marginal product of labor and the marginal cost of production:

- The marginal product of labor is *rising* for the first two workers, but the marginal cost of the pizzas produced by these workers is *falling*.

MyEconLab Animation

Figure 11.4

Jill Johnson's Marginal Cost and Average Total Cost of Producing Pizzas

We can use the information in the table to calculate Jill's marginal cost and average total cost of producing pizzas. For the first two workers hired, the marginal product of labor is increasing, which causes the marginal cost of production to fall. For the last four workers hired, the marginal product of labor is falling, which causes the marginal cost of production to increase. Therefore, the marginal cost curve falls and then rises—that is, has a U shape—because the marginal product of labor rises and then falls. As long as marginal cost is below average total cost, average total cost will be falling. When marginal cost is above average total cost, average total cost will be rising. The relationship between marginal cost and average total cost explains why the average total cost curve also has a U shape.

Quantity of Workers	Quantity of Pizzas	Marginal Product of Labor	Total Cost of Pizzas	Marginal Cost of Pizzas	Average Total Cost of Pizzas
0	0	—	\$800	—	—
1	200	200	1,450	\$3.25	\$7.25
2	450	250	2,100	2.60	4.67
3	550	100	2,750	6.50	5.00
4	600	50	3,400	13.00	5.67
5	625	25	4,050	26.00	6.48
6	640	15	4,700	43.33	7.34

- The marginal product of labor is *falling* for the last four workers, but the marginal cost of pizzas produced by these workers is *rising*.

We can generalize what the table shows us: *When the marginal product of labor is rising, the marginal cost of output is falling. When the marginal product of labor is falling, the marginal cost of output is rising.*

One way to understand the relationship between the marginal product of labor and the marginal cost of output is to notice that the only additional cost to Jill from producing more pizzas is the additional wages she pays to hire more workers. She pays each new worker the same \$650 per week. So the marginal cost of the additional pizzas each worker makes depends on that worker's additional output, or marginal product. As long as the additional output from each new worker is rising, the marginal cost of that output is falling. When the additional output from each new worker is falling, the marginal cost of that output is rising. *We can conclude that the marginal cost of output falls and then rises—forming a U shape—because the marginal product of labor rises and then falls.*

The relationship between marginal cost and average total cost follows the usual relationship between marginal and average values. As long as marginal cost is below average total cost, average total cost falls. When marginal cost is above average total cost, average total cost rises. Marginal cost equals average total cost when average total cost is at its lowest point. Therefore, the average total cost curve has a U shape because the marginal cost curve has a U shape.

Calculating Marginal Cost and Average Cost

Santiago Delgado owns a copier store. He leases two copy machines for which he pays \$12.50 each per day. He cannot increase the number of machines he leases without giving the office machine company six weeks' notice. He can hire as many workers as he wants, at a cost of \$50 per day per worker. These are the only two inputs he uses to produce copies.

- Fill in the remaining columns in the table by using the definitions of costs.
- Draw the average total cost curve and marginal cost curve for Santiago's store. Do these curves have the expected shape? Briefly explain.

Quantity of Workers	Quantity of Copies per Day	Fixed Cost	Variable Cost	Total Cost	Average Total Cost	Marginal Cost
0	0					
1	625					
2	1,325					
3	2,200					
4	2,600					
5	2,900					
6	3,100					

Solving the Problem

Step 1: Review the chapter material. This problem requires you to understand definitions of costs, so you may want to review the section “The Difference between Fixed Costs and Variable Costs,” which begins on page 425, and the section “Why Are the Marginal and Average Cost Curves U Shaped?” which begins on page 433.

Step 2: Answer part (a) by using the definitions of costs. Santiago's fixed cost is the amount he pays to lease the copy machines. He uses two copy machines and pays \$12.50 each to lease them, so his fixed cost is \$25. Santiago's variable cost is the amount he pays to hire workers. He pays \$50 per worker per day. His total cost is the sum of his fixed cost and his variable cost. His average total cost is his total cost divided by the quantity of copies he produces that day. His marginal cost is the change in total cost divided by the change in output. For example, his marginal cost of producing 1,325 copies per day, rather than 625 copies, is:

$$MC = (\$125 - \$75)/(1,325 - 625) = \$0.07.$$

Quantity of Workers	Quantity of Copies per Day	Fixed Cost	Variable Cost	Total Cost	Average Total Cost	Marginal Cost
0	0	\$25	\$0	\$25	—	—
1	625	25	50	75	\$0.12	\$0.08
2	1,325	25	100	125	0.09	0.07
3	2,200	25	150	175	0.08	0.06
4	2,600	25	200	225	0.09	0.13
5	2,900	25	250	275	0.09	0.17
6	3,100	25	300	325	0.10	0.25

Step 3: Answer part (b) by drawing the average total cost and marginal cost curves for Santiago's store and by explaining whether they have the usual shape. Use the numbers from the table to draw your graph:

We expect average total cost and marginal cost curves to have a U shape, which Santiago's cost curves do. Both cost curves fall and then rise in the same way as the cost curves in Figure 11.4 on page 434.

11.5 Graphing Cost Curves

LEARNING OBJECTIVE: Graph average total cost, average variable cost, average fixed cost, and marginal cost.

Average fixed cost Fixed cost divided by the quantity of output produced.

Average variable cost Variable cost divided by the quantity of output produced.

We have seen that we calculate average total cost by dividing total cost by the quantity of output produced. Similarly, we can calculate **average fixed cost** by dividing fixed cost by the quantity of output produced. And we can calculate **average variable cost** by dividing variable cost by the quantity of output produced. We can present these three measures of cost mathematically (with Q representing the level of output) as:

$$\text{Average total cost} = ATC = \frac{TC}{Q}$$

$$\text{Average fixed cost} = AFC = \frac{FC}{Q}$$

$$\text{Average variable cost} = AVC = \frac{VC}{Q}$$

Finally, notice that average total cost is the sum of average fixed cost plus average variable cost:

$$ATC = AFC + AVC.$$

The only fixed cost Jill incurs in operating her restaurant is the \$800 per week she pays on the bank loan for her pizza ovens. Her variable costs are the wages she pays her workers. The table and graph in Figure 11.5 show Jill's costs.

We will use graphs like the one in Figure 11.5 in the next several chapters to analyze how firms decide the level of output to produce and the price to charge. Before going further, be sure you understand the following three key facts about Figure 11.5:

1. The marginal cost (MC), average total cost (ATC), and average variable cost (AVC) curves are all U shaped, and the marginal cost curve intersects both the average

1	2	200	800	650	1,450	\$7.25	\$4.00	\$3.25	\$3.25
2	2	450	800	1,300	2,100	4.67	1.78	2.89	2.60
3	2	550	800	1,950	2,750	5.00	1.45	3.54	6.50
4	2	600	800	2,600	3,400	5.67	1.33	4.33	13.00

6	2	640	800	3,900	4,700	7.34	1.25	6.09	43.33

Jill’s costs of making pizzas are shown in the table and plotted in the graph. Notice three important facts about the graph: (1) The marginal cost (MC), average total cost (ATC), and average variable cost (AVC) curves are all U shaped, and the marginal cost curve intersects both the average variable cost curve and the average total cost curve at their minimum points. (2) As output increases, average fixed cost (AFC) gets smaller and smaller. (3) As output increases, the difference between average total cost and average variable cost decreases. Make sure you can explain why each of these three facts is true. You should spend time becoming familiar with this graph because it is one of the most important graphs in microeconomics.

variable cost curve and the average total cost curve at their minimum points. When marginal cost is below either average variable cost or average total cost, it causes them to decrease. When marginal cost is above average variable cost or average total cost, it causes them to increase. Therefore, when marginal cost equals average variable cost or average total cost, they must be at their minimum points.

- As output increases, average fixed cost gets smaller and smaller. This result occurs because in calculating average fixed cost, we are dividing something that gets larger and larger—output—into something that remains constant—fixed cost. Firms often refer to this process of lowering average fixed cost by selling more output as “spreading the overhead” (where “overhead” refers to fixed costs).
- As output increases, the difference between average total cost and average variable cost decreases. This result occurs because the difference between average total cost and average variable cost is average fixed cost, which gets smaller as output increases.

11.6 Costs in the Long Run

LEARNING OBJECTIVE: Understand how firms use the long-run average cost curve in their planning.

The distinction between fixed cost and variable cost that we just discussed applies to the short run but *not* to the long run. For example, in the short run, Jill Johnson has fixed costs of \$800 per week because she signed a loan agreement with a bank when she bought her pizza ovens. But in the long run, the cost of buying more pizza ovens becomes variable because Jill can choose whether to expand her business by buying more of them. The same would be true of any other fixed costs a company like Jill's might have. Once a company has purchased a fire insurance policy, the cost of the policy is fixed. But when the policy expires, the company must decide whether to renew it, and the cost becomes variable. The important point is: *In the long run, all costs are variable. There are no fixed costs in the long run.* In other words, in the long run, total cost equals variable cost, and average total cost equals average variable cost.

Managers of successful firms simultaneously consider how they can most profitably run their current store, factory, or office and also whether in the long run they would be more profitable if they became larger or, possibly, smaller. Jill must consider how to run her current restaurant, which has only two pizza ovens, and she must also plan what to do when her current bank loan is paid off and the lease on her store ends. Should she buy more pizza ovens? Should she lease a larger restaurant?

Economies of Scale

Short-run average cost curves represent the costs a firm faces when some input, such as the quantity of machines it uses, is fixed. The **long-run average cost curve** shows the lowest cost at which a firm is able to produce a given quantity of output in the long run, when no inputs are fixed. A firm may experience **economies of scale**, which means the firm's long-run average costs fall as it increases the quantity of output it produces. We can see the effects of economies of scale in Figure 11.6, which shows the relationship between short-run and long-run average cost curves. Managers can use long-run average cost curves for planning because they show the effect on cost of expanding output by, for example, building a larger factory or restaurant.

Figure 11.6

The Relationship between Short-Run Average Cost and Long-Run Average Cost

If a small car company expects to sell only 20,000 cars per year, it will be able to produce cars at the lowest average cost of \$52,000 per car if it builds the small factory represented by the ATC curve on the left of the figure. A larger factory will be able to produce 200,000 cars per year at a lower cost of \$27,000 per car. An automobile factory producing 200,000 cars per year and a factory producing 400,000 cars per year will experience constant returns to scale and have the same average cost. An automobile factory assembling 200,000 cars per year will have reached minimum efficient scale. Very large automobile factories will experience diseconomies of scale, and their average costs will rise as production increases beyond 400,000 cars per year.

Long-Run Average Cost Curves for Automobile Factories

Figure 11.6 shows long-run average cost in the automobile industry. If a small company, such as Tesla Motors, expects to sell only 20,000 cars per year, then it will be able to assemble cars at the lowest average cost of \$52,000 per car if it builds a small factory, as represented by the ATC curve on the left of the figure. A much larger factory, such as those operated by Ford, General Motors, and Toyota, will be able to produce 200,000 cars per year at a lower average cost of \$27,000 per car. This decline in average cost from \$52,000 to \$27,000 represents the economies of scale that exist in manufacturing automobiles. Why would the larger automobile factory have lower average costs? One important reason is that a company like Ford is producing 10 times as many cars per year in one of its factories as Tesla produces in its factory but might need only 6 times as many workers. This saving in labor cost would reduce Ford's average cost of selling cars.

In general, firms may experience economies of scale for a number of reasons, with these being the most important:

1. As in the case of automobile production, the firm's technology may make it possible to increase production with a smaller proportional increase in at least one input.
2. Both workers and managers can become more specialized, enabling them to become more productive, as output expands.
3. Large firms, like Ford, Walmart, or Apple, may be able to purchase inputs at lower costs than smaller competitors. In fact, as Apple and Walmart expanded, their bargaining power with their suppliers increased, and their average costs fell.
4. As a firm expands, it may be able to borrow money at a lower interest rate, thereby lowering its costs.

Economies of scale do not continue indefinitely as the firm increases its output. The long-run average cost curve in most industries has a flat segment that often stretches over a substantial range of output. As Figure 11.6 shows, an automobile factory producing 200,000 cars per year and a factory producing 400,000 cars per year have the same average cost. Over this range of output, firms in the industry experience **constant returns to scale**. As these firms increase their output, they increase their inputs, such as the size of the factory and the quantity of workers, proportionally. The level of output at which all economies of scale are exhausted is known as **minimum efficient scale**. An automobile factory producing 200,000 cars per year has reached minimum efficient scale. Firms that produce at less than minimum efficient scale may have difficulty surviving because they will be producing output at higher cost than competitors.

Very large automobile factories experience increasing average costs as managers begin to have difficulty coordinating the operation of the factory. Figure 11.6 shows that for production above 400,000 cars per year, firms in the industry experience **diseconomies of scale**. For instance, Toyota found that as it expanded production at its Georgetown, Kentucky, plant and its plants in China, its managers had difficulty keeping average cost from rising. According to the president of Toyota's Georgetown plant: "Demand for ... high volumes saps your energy. Over a period of time, it eroded our focus ... [and] thinned out the expertise and knowledge we painstakingly built up over the years." One analysis of the problems Toyota faced in expanding production concluded: "It is the kind of paradox many highly successful companies face: Getting bigger doesn't always mean getting better."

MyEconLab Concept Check

Constant returns to scale

The situation in which a firm's long-run average costs remain unchanged as it increases output.

Minimum efficient scale The level of output at which all economies of scale are exhausted.

Diseconomies of scale

The situation in which a firm's long-run average costs rise as the firm increases output.

Solved Problem 11.6

Using Long-Run Average Cost Curves to Understand Business Strategy

Medium trucks are larger than pickup trucks and are primarily purchased by construction firms and other businesses. Ford has a successful line of F-series pickup trucks.

In 2015, Ford announced plans to start building medium trucks in its factory in Avon Lake, Ohio. According to an article in the *Wall Street Journal*, Ford's new medium trucks

MyEconLab Interactive Animation

“would share engines, transmissions and cab components with its other F-series vehicles to build economies of scale.” According to the same article, Ford’s new medium truck would have costs that were \$5,000 less per vehicle than the similar trucks produced by competing firms.

- a. Explain what the article means by saying Ford intends “to build economies of scale” means.

- b. Use a long-run average cost curve to illustrate Ford’s strategy.
- c. What does the article allow us to conclude about the operations of Ford’s competitors?

Solving the Problem

Step 1: Review the chapter material. This problem is about the long-run average cost curve, so you may want to review the material in the section “Costs in the Long Run,” which begins on page 438.

Step 2: Answer part (a) by explaining what the article means by saying that Ford intends “to build economies of scale.” By producing many of the components of its new medium trucks in the same factory where it produces its F-series trucks, Ford intends to lower its average cost by increasing its output. In other words, by expanding its factory, Ford is taking advantage of economies of scale in truck production.

Step 3: Answer part (b) by drawing a long-run average cost graph for Ford’s truck factory. For Ford’s strategy to be successful, its factory must not currently be at minimum efficient scale. In the following graph, we assume that Ford is currently producing at point A on its long-average cost curve, where truck output equals Q_1 and average total cost equals Average cost₁. Ford’s strategy is to expand production to point B, where truck output equals Q_2 and average total cost equals Average cost₂.

Step 4: Answer part (c) by explaining what we can conclude about the operations of Ford’s competitors. After expanding its truck factory, Ford’s average cost of producing trucks will be \$5,000 less per vehicle than its competitors. We can conclude that Ford’s competitors are failing to take advantage of economies of scale in truck production. The competitors’ factories are apparently operating below minimum efficient scale.

Source: Bob Tita, “Navistar Steels Itself for Ford Business Loss,” *Wall Street Journal*, May 12, 2014.

Over time, most firms in an industry will build factories or stores that are at least as large as the minimum efficient scale but not so large that diseconomies of scale occur. For example, in the automobile industry, most factories will produce between 200,000 and 400,000 cars per year. However, firms often do not know the exact shape of their long-run average cost curves. As a result, they may mistakenly build factories or stores that are either too large or too small.

The Colossal River Rouge: Diseconomies of Scale at Ford Motor Company

When Henry Ford started the Ford Motor Company in 1903, automobile companies produced cars in small workshops, using highly skilled workers. Ford introduced two new ideas to the automobile industry that allowed him to take advantage of economies of scale. First, Ford used identical—or, interchangeable—parts so that unskilled workers could assemble the cars. Second, instead of having groups of workers moving from one stationary automobile to the next, he had the workers remain stationary, while the automobiles moved along an assembly line. Ford built a large factory at Highland Park, outside Detroit, where he used these ideas to produce the famous Model T at an average cost well below what his competitors could match using older production methods in smaller factories.

Ford believed that he could produce automobiles at an even lower average cost by building a still larger plant along the River Rouge in Dearborn, Michigan. Unfortunately, Ford's River Rouge plant was too large and suffered from diseconomies of scale. Ford's managers had great difficulty coordinating the production of automobiles in such a large plant. The following description of the River Rouge plant comes from a biography of Ford by Allan Nevins and Frank Ernest Hill:

A total of 93 separate structures stood on the [River Rouge] site . . . Railroad trackage covered 93 miles, conveyors 27 [miles]. About 75,000 men worked in the great plant. A force of 5000 did nothing but keep it clean, wearing out 5000 mops and 3000 brooms a month, and using 86 tons of soap on the floors, walls, and 330 acres of windows. The Rouge was an industrial city, immense, concentrated, packed with power . . . By its very massiveness and complexity, it denied men at the top contact with and understanding of those beneath, and gave those beneath a sense of being lost in inexorable immensity and power.

Beginning in 1927, Ford produced the Model A—its only car model at that time—at the River Rouge plant. Ford failed to achieve economies of scale and actually *lost money* on each of the four Model A body styles.

Ford could not raise the price of the Model A to make it profitable because at a higher price, the car could not compete with similar models produced by competitors such as General Motors and Chrysler. Ford eventually reduced the cost of making the Model A by constructing smaller factories spread out across the country. These smaller factories produced the Model A at a lower average cost than was possible at the River Rouge plant.

Don't Let This Happen to You

Don't Confuse Diminishing Returns with Diseconomies of Scale

The concepts of diminishing returns and diseconomies of scale may seem similar, but they are actually unrelated. Diminishing returns applies only to the short run, when at least one of the firm's inputs, such as the quantity of machinery it uses, is fixed. The law of diminishing returns tells us that in the short run, hiring more workers will, at some point, result in less additional output. Diminishing returns explains why marginal cost curves eventually

slope upward. Diseconomies of scale apply only in the long run, when the firm is free to vary all its inputs, can adopt new technology, and can vary the amount of machinery it uses and the size of its facility. Diseconomies of scale explain why long-run average cost curves eventually slope upward.

Economics in Your Life

Using Cost Concepts in Your Online Business

At the beginning of the chapter, we asked you to suppose that you are about to start a Web site to sell iPhone cases. Both you and your friend José can buy cases from the manufacturer for \$10 each. But because José sells more cases per month than you expect to be able to sell, his costs per case are lower than yours. We asked you to think about why this might be true.

In this chapter, we have seen that firms often experience declining average costs as the quantity they sell increases. A key reason José's average costs might be lower than yours has to do with fixed costs. Because you will have the same computers and software and rent an office similar to José's, you may be paying about the same amount for equipment and an office lease. You may also be paying about the same amounts for utilities, insurance, and advertising. All these are fixed costs because they do not change as the quantity of cases you sell changes. Because José's fixed costs are the same as yours, but he is selling more cases, his average fixed costs are lower than yours, and, therefore, so are his average total costs. With lower average total costs, he can sell his cases for a lower price than you do and still make a profit.

Conclusion

In this chapter, we discussed the relationship between a firm's technology, production, and costs. We encountered a number of definitions of costs. Because we will use these definitions in later chapters, it is useful to bring them together in Table 11.4 for you to review.

We have seen the important relationship between a firm's level of production and its costs. This information is vital to all firms as they attempt to decide the optimal level of production and the optimal prices to charge for their products. We will explore this point further in the next chapter.

Technology: An Economic Definition, pages 424–425

LEARNING OBJECTIVE: Define technology and give examples of technological change.

Summary

The basic activity of a firm is to use inputs, such as workers, machines, and natural resources, to produce goods and services. The firm's **technology** is the processes it uses to turn inputs into goods and services. **Technological change** refers to a change in the ability of a firm to produce a given level of output with a given quantity of inputs.

The Short Run and the Long Run in Economics, pages 425–429

LEARNING OBJECTIVE: Distinguish between the economic short run and the economic long run.

Summary

In the **short run**, a firm's technology and the size of its factory, store, or office are fixed. In the **long run**, a firm is able to adopt new technology and increase or decrease the size of its physical plant. **Total cost** is the cost of all the inputs a firm uses in production. **Variable costs** are costs that change as output changes. **Fixed costs** are costs that remain constant as output changes. **Opportunity cost** is the highest-valued alternative that must be

given up to engage in an activity. An **explicit cost** is a cost that involves spending money. An **implicit cost** is a nonmonetary opportunity cost. The relationship between the inputs employed by a firm and the maximum output it can produce with those inputs is called the firm's **production function**.

Jill is considering selling her building and renting space in the suburbs for \$3,000 per month, but she decides not to make the move. She reasons: "I would like to have a restaurant in the suburbs, but I pay no rent for my restaurant now, and I don't want to see my costs rise by \$3,000 per month." Evaluate Jill's reasoning.

- 2.12 The emissions-fixing scandal that engulfed the German car manufacturer, Volkswagen, in the United States could extend to other companies and countries, one of the officials involved in uncovering the alleged behavior told *The Guardian*. Billions of pounds were wiped off the value of global carmakers amid growing concerns that emission tests may have been rigged across the industry. A British expert in low-emission vehicles claimed the manipulation of air pollution data could be "very widespread" and that tests in Europe are "much more open to this sort of abuse". What kind of costs is Volkswagen facing? Briefly explain.

11.3 The Marginal Product of Labor and the Average Product of Labor, pages 429–433

LEARNING OBJECTIVE: Understand the relationship between the marginal product of labor and the average product of labor.

Summary

The **marginal product of labor** is the additional output produced by a firm as a result of hiring one more worker. Specialization and division of labor cause the marginal product of labor to rise for the first few workers hired. Eventually, the **law of diminishing returns** causes the marginal product of labor to decline. The **average product of labor** is the total amount of output produced by a firm divided by the quantity of workers hired. When the marginal product of labor is greater than the average product of labor, the average product of labor increases. When the marginal product of labor is less than the average product of labor, the average product of labor decreases.

Review Questions

- Draw a graph that shows the usual relationship between the marginal product of labor and the average product of labor. Why do the marginal product of labor and the average product of labor curves have the shapes you drew?
- How do specialization and division of labor typically affect the marginal product of labor?
- What is the law of diminishing returns? Does it apply in the long run?

Problems and Applications

- 3.4 Fill in the missing values in the following table.

Quantity of Workers	Total Output	Marginal Product of Labor	Average Product of Labor
0	0		
1	400		
2	900		
3	1,500		
4	1,900		
5	2,200		
6	2,400		
7	2,300		

- 3.5 Use the numbers from problem 3.4 to draw one graph that shows how total output increases with the quantity of workers hired and a second graph that shows the marginal product of labor and the average product of labor.

- 3.6 A student looks at the numbers in Table 11.3 on page 429 and draws this conclusion:

The marginal product of labor is increasing for the first two workers hired, and then it declines for the next four workers. I guess each of the first two workers must have been hard workers. Then Jill must have had to settle for increasingly bad workers.

Do you agree with the student's analysis? Briefly explain.

- 3.7 (Related to the **Making the Connection on page 431**) Briefly explain whether you agree with the following argument:

Adam Smith's idea of the gains to firms from the division of labor makes a lot of sense when the good being manufactured is something complex like automobiles or computers, but it doesn't apply in the manufacturing of less complex goods or in other sectors of the economy, such as retail sales.

- 3.8 Sally looks at her college transcript and asks you, "How is this possible? My grade point average for this semester's courses is higher than my grade point average for last semester's courses, but my cumulative grade point average still went down from last semester to this semester." Explain to Sally how this is possible.
- 3.9 Is it possible for a firm to experience a technological change that would increase the marginal product of labor while leaving the average product of labor unchanged? Explain.

- When the owner hires 4 workers, what is average product of labor?
- What is the marginal product of the fifth worker?
- If the marginal product of the second worker is 6, what is the total number of pizzas produced when 2 workers are hired?
- Assuming that the marginal product of the second worker is 6, with which worker hired does the law of diminishing returns set in?

11.4

The Relationship between Short-Run Production and Short-Run Cost, pages 433–436

LEARNING OBJECTIVE: Explain and illustrate the relationship between marginal cost and average total cost.

Summary

The **marginal cost** of production is the increase in total cost that results from producing another unit of output. The marginal cost curve has a U shape because when the marginal product of labor is rising, the marginal cost of output is falling, and when the marginal product of labor is falling, the marginal cost of output is rising. When marginal cost is less than average total cost, average total cost falls. When marginal cost is greater than average total cost, average total cost rises. Therefore, the average total cost curve also has a U shape.

Review Questions

- 4.1 What is the difference between the average cost of production and the marginal cost of production?
- 4.2 If the marginal product of labor is rising, is the marginal cost of production rising or falling? Briefly explain.
- 4.3 Explain why the marginal cost curve intersects the average total cost curve at the level of output where average total cost is at a minimum.

Problems and Applications

- 4.4 Codelco, a state-owned Chilean group, is the world's single biggest copper producer, producing about 1.76 million metric tons of copper a year. BHP Billiton, the Australian group, produces about 1.14 million metric tons of copper a year. The marginal cost of producing another metric ton of copper is around \$9000. In making the calculation, the cost of labor, materials, and other inputs that increase when more copper is produced are taken into account. The CEO of BHP Billiton decides to take a bank loan to improve its revenues, but the Board says: "If we take into account the amount we pay on this loan, it adds \$1000 per metric ton of copper to our marginal cost of production." Do you agree with this aspect? Briefly explain.
- 4.5 Is it possible for average total cost to be decreasing over a range of output where marginal cost is increasing? Briefly explain.
- 4.6 Suppose a firm has no fixed costs, so all its costs are variable, even in the short run.
 - a. If the firm's marginal costs are continually increasing (that is, marginal cost is increasing from the first unit of output produced), will the firm's average total cost curve have a U shape?
 - b. If the firm's marginal costs are \$5 at every level of output, what shape will the firm's average total cost have?
- 4.7 (Related to Solved Problem 11.4 on page 435) Santiago Delgado owns a copier store. He leases two copy machines for which he pays \$20 each per day. He cannot increase the number of machines he leases without giving the office machine company six weeks' notice. He can hire as many workers as he wants, at a cost of \$40 per day per worker. These are the only two inputs he uses to produce copies.

- a. Fill in the remaining columns in the following table.
- b. Draw the average total cost curve and marginal cost curve for Santiago's store. Do these curves have the expected shape? Briefly explain.

Quantity of Workers	Quantity of Copies per Day	Fixed Cost	Variable Cost	Total Cost	Average Total Cost	Marginal Cost

- 4.8 You possess the following information: current output of a firm amounts to 150 units and the corresponding total cost is €1,500. Should production of the firm increase to 151 units, the total cost would increase to €1,505. Is it sufficient to conclude that the marginal cost is increasing? Draw a graph to illustrate your answer.
- 4.9 The following information is provided to you: current output amounts to 150 units and the corresponding total cost is €1,500. Should production increase to 151 units, total cost would rise to €1,515. Is the given data sufficient to conclude that the marginal cost is increasing? Illustrate your answer using a graph.
- 4.10 (This problem is somewhat advanced.) Using symbols, we can write that the marginal product of labor is equal to $\Delta Q/\Delta L$. Marginal cost is equal to $\Delta TC/\Delta Q$. Because fixed costs by definition don't change, marginal cost is also equal to $\Delta VC/\Delta Q$. If Jill Johnson's only variable cost (VC) is labor cost, then her variable cost equals the wage multiplied by the quantity of workers hired, or wL .
 - a. If the wage Jill pays is constant, then what is ΔVC in terms of w and L ?
 - b. Use your answer to part (a) and the expressions given for the marginal product of labor and the marginal cost of output to find an expression for marginal cost, $\Delta TC/\Delta Q$, in terms of the wage, w , and the marginal product of labor, $\Delta Q/\Delta L$.
 - c. Use your answer to part (b) to determine Jill's marginal cost of producing pizzas if the wage is \$750 per week and the marginal product of labor is 150 pizzas. If the wage falls to \$600 per week and the marginal product of labor is unchanged, what happens to Jill's marginal cost? If the wage is unchanged at \$750 per week and the marginal product of labor rises to 250 pizzas, what happens to Jill's marginal cost?

11.5 Graphing Cost Curves, pages 436–437

LEARNING OBJECTIVE: Graph average total cost, average variable cost, average fixed cost, and marginal cost.

Summary

Average fixed cost is equal to fixed cost divided by the level of output. **Average variable cost** is equal to variable cost divided by the level of output. Figure 11.5 on page 437 shows the relationship among marginal cost, average total cost, average variable cost, and average fixed cost. It is one of the most important graphs in microeconomics.

Review Questions

- 5.1 Where does the marginal cost curve intersect the average variable cost curve and the average total cost curve?
- 5.2 Explain why the average fixed cost always decreases as the level of output increases, and what it implies for the average total cost.

Problems and Applications

- 5.3 Suppose the total cost of producing 10,000 tennis balls is \$30,000 and the fixed cost is \$10,000.
 - a. What is the variable cost?
 - b. When output is 10,000, what are the average variable cost and the average fixed cost?
 - c. Assume that the cost curves have the usual shape. Is the dollar difference between the average total cost and the average variable cost greater when the output is 10,000 tennis balls or when the output is 30,000 tennis balls? Explain.
- 5.4 One description of the costs of operating a railroad makes the following observation: “The fixed ... expenses which attach to the operation of railroads ... are in the nature of a tax upon the business of the road; the smaller the [amount of] business, the larger the tax.” Briefly explain why fixed costs are like a tax. In what sense is this tax smaller when the amount of business is larger?

- 5.5 In the ancient world, a book could be produced either on a scroll or as a codex, which was made of folded sheets glued together, something like a modern book. One scholar has estimated the following variable costs (in Greek drachmas) of the two methods:

	Scroll	Codex
Cost of writing (wage of a scribe)	11.33 drachmas	11.33 drachmas
Cost of paper	16.50 drachmas	9.25 drachmas

Another scholar points out that a significant fixed cost was involved in producing a codex:

In order to copy a codex ... the amount of text and the layout of each page had

to be carefully calculated in advance to determine the exact number of sheets ... needed. No doubt, this is more time-consuming and calls for more experimentation than the production of a scroll would. But for the next copy, these calculations would be used again.

- a. Suppose that the fixed cost of preparing a codex was 58 drachmas and that there was no similar fixed cost for a scroll. Would an ancient book publisher who intended to sell 5 copies of a book be likely to publish it as a scroll or as a codex? What if he intended to sell 10 copies? Briefly explain.
- b. Although most books were published as scrolls in the first century A.D., by the third century, most were published as codices. Considering only the factors mentioned in this problem, explain why this change may have taken place.

- 5.6 (Related to the Chapter Opener on page 423) We saw in the chapter opener that some colleges and private companies have launched online courses that anyone with an Internet connection can take. The most successful of these massive open online courses (MOOCs) have attracted tens of thousands of students. Suppose that your college offers a MOOC and spends a total of \$200,000 on one-time costs to have instructors prepare the course material and to buy additional server capacity. The college administration estimates that the variable cost of offering the course will be \$20 per student per course. This variable cost is the same, regardless of how many students enroll in the course.

1,000				
10,000				
20,000				

- b. Use your answer to part (a) to draw a cost curve graph to illustrate your college’s costs of offering this course. Your graph should measure cost on the vertical axis and the quantity of students taking the course on the horizontal axis. Be sure your graph contains the following curves: average total cost, average variable cost, average fixed cost, and marginal cost.

5.7 Use the information in the graph to find the values for the following at an output level of 1,000.

- Marginal cost
 - Total cost
 - Variable cost
 - Fixed cost
- 5.8 List the errors in the following graph. Carefully explain why the curves drawn this way are incorrect. In other words, why can't these curves be as they are shown in the graph?

- 5.9 Explain how the events listed in (a) through (d) would affect the following costs of a firm producing cups:
- Marginal cost
 - Average variable cost
 - Average fixed cost
 - Average total cost
 - Following the burst of a housing market boom, the cost of renting the warehouse significantly decreases.
 - The cost of clay used to make the cups goes up.

Costs in the Long Run, pages 438–442

LEARNING OBJECTIVE: Understand how firms use the long-run average cost curve in their planning.

Summary

The **long-run average cost curve** shows the lowest cost at which a firm is able to produce a given level of output in the long run. For many firms, the long-run average cost curve falls as output expands because of **economies of scale**. **Minimum efficient scale** is the level of output at which all economies of scale have been exhausted. After economies of scale have been exhausted, firms experience **constant returns to scale**, where their long-run average cost curve is flat. At high levels of output, the long-run average cost curve turns up as the firm experiences **diseconomies of scale**.

Review Questions

- Is the time horizon relevant when considering fixed and variable costs? Briefly explain your answer.
- What is minimum efficient scale? What is likely to happen in the long run to firms that do not reach minimum efficient scale?
- What are economies of scale? What are four reasons that firms may experience economies of scale?

- Do you think diseconomies of scale are possible? What would it mean for a firm? Briefly explain your answer by mentioning a real life example.

Problems and Applications

- An article in the *Wall Street Journal* described the Chinese automobile industry as “a hodgepodge of companies,” most of which produce fewer than 100,000 cars per year. Ford Chief Executive Alan Mulally commented on the situation by saying, “If you don’t have scale, you just won’t be able to be competitive.”

- A student asks, "If the average cost of producing pizzas is lower in the larger restaurant when Jill produces 7,500 pizzas per week, why isn't it also lower when Jill produces 5,200 pizzas per week?" Give a brief answer to the student's question.

6.8 (Related to Solved Problem 11.6 on page 439) An article in the *Wall Street Journal* discussed the proposal of a merger between Canadian Pacific Railway Ltd. and Norfolk Southern Corporation. The article predicted that a merger with Norfolk Southern would create an industry giant with a combined market value of about \$47 billion, and a rail network that would stretch from the Canadian West Coast to the Gulf of Mexico and U.S. Atlantic seaboard. There would be little overlap between the rail networks, something that could promote efficiency, at a time when both railroads are facing declining freight volumes. However, Norfolk Southern has problems in achieving economies of scale and was criticized for poor service and failing to cut costs quickly enough when volumes and freight traffic were declining.

- What economies of scale may exist in this kind of industry?
- What does the article mean by efficiency that might be gained through this merger?
- If Canadian Pacific Railway had already achieved minimum efficient scale before the proposed merger with Norfolk, why the merger itself is thought to be more efficient? Briefly explain.

6.11 Due to the inimitable manufacturing processes of 3D printing, people now have the ability to innovate products from the inside out. The process cannot be mimicked using traditional manufacturing methods because 3D printing is an additive process. This means that individuals and businesses alike can create internal skeletal structures and unique shapes within an object. Thus, the economies of scale in 3D printing may be considerably smaller than in conventional 2D printing. If this view is correct, what would be the consequences for the printing companies in the United States?

6.12 (Related to the Don't Let This Happen to You on page 442) More than one in six workers in Britain's steel industry is facing the axe after Tata Steel confirmed it was cutting 1,200 jobs. Tata, which owns the remnants of the former British Steel, blamed cheap Chinese imports, the strong pound, and high electricity costs for its decision to stop production of steel plate. Karl Köhler, chief executive of Tata Steel's European operations, said:

The U.K. steel industry is struggling for survival in the face of extremely challenging market conditions. This industry has a crucial role to play in rebalancing the U.K. economy, but we need a fairer system to encourage growth.

Is this an example of diminishing returns or diseconomies of scale? Briefly explain.

6.13 In September, 2015, tough export markets and weaker consumer spending continued to take their toll on factories in Britain, prompting the first job losses for the sector in more than two years, according to a survey that echoed signs of manufacturing weakness around the world. Against the backdrop of warnings about the uncertain outlook for global growth, Eurozone manufacturing also lost momentum and output from Chinese factories continued to fall. Kallum Pickering, a senior economist at Berenberg Bank, the United Kingdom, said in the medium term rising demand from the United Kingdom's biggest and closest trading partners should help underpin a recovery in manufacturing.

- What did Pickering mean by 'medium term rising demand should help underpin a recovery in manufacturing'?

Appendix

Using Isoquants and Isocost Lines to Understand Production and Cost

LEARNING OBJECTIVE: Use isoquants and isocost lines to understand production and cost.

Isoquants

In this chapter, we studied the important relationship between a firm's level of production and its costs. In this appendix, we look more closely at how firms choose the combination of inputs to produce a given level of output. Firms usually have a choice about how they will produce their output. For example, Jill Johnson is able to produce 5,000 pizzas per week by using 10 workers and 2 ovens or by using 6 workers and 3 ovens. We will see that firms search for the *cost-minimizing* combination of inputs that will allow them to produce a given level of output. The cost-minimizing combination of inputs depends on two factors: technology—which determines how much output a firm receives from employing a given quantity of inputs—and input prices—which determine the total cost of each combination of inputs.

An Isoquant Graph

We begin by graphing the levels of output that Jill can produce using different combinations of two inputs: labor—the quantity of workers she hires per week—and capital—the quantity of ovens she uses per week. In reality, of course, Jill uses more than just these two inputs to produce pizzas, but nothing important would change if we expanded the discussion to include many inputs instead of just two. Figure 11A.1 measures the quantity of capital along the vertical axis and the quantity of labor along the horizontal axis. The curves in the graph are **isoquants**, which show all the combinations of two inputs—in this case capital and labor—that will produce the same level of output.

Isoquant A curve that shows all the combinations of two inputs, such as capital and labor, that will produce the same level of output.

MyEconLab Animation

Figure 11A.1

Isoquants

Isoquants show all the combinations of two inputs—in this case capital and labor—that will produce the same level of output. For example, the isoquant labeled $Q = 5,000$ shows all the combinations of ovens and workers that enable Jill to produce that quantity of pizzas per week. At point A, she produces 5,000 pizzas using 3 ovens and 6 workers, and at point B, she produces the same output using 2 ovens and 10 workers. With more ovens and workers, she can move to a higher isoquant. For example, with 4 ovens and 12 workers, she can produce at point C on the isoquant $Q = 10,000$. With even more ovens and workers, she could move to the isoquant $Q = 13,000$.

The isoquant labeled $Q = 5,000$ shows all the combinations of workers and ovens that enable Jill to produce that quantity of pizzas per week. For example, at point A, she produces 5,000 pizzas using 6 workers and 3 ovens, and at point B, she produces the same output using 10 workers and 2 ovens. With more workers and ovens, she can move to a higher isoquant. For example, with 12 workers and 4 ovens, she can produce at point C on the isoquant $Q = 10,000$. With even more workers and ovens, she could move to the isoquant $Q = 13,000$. The higher the isoquant—that is, the further to the upper right on the graph—the more output the firm produces. Although we have shown only three isoquants in this graph, there is, in fact, an isoquant for every level of output.

MyEconLab Concept Check

The Slope of an Isoquant

Remember that the slope of a curve is the ratio of the change in the variable on the vertical axis to the change in the variable on the horizontal axis. Along an isoquant, the slope tells us the rate at which a firm is able to substitute one input for another while keeping the level of output constant. This rate is called the **marginal rate of technical substitution (MRTS)**.

We expect that the MRTS will change as we move down an isoquant. In Figure 11A.1, at a point like A on isoquant $Q = 5,000$, the isoquant is relatively steep. As we move down the curve, it becomes less steep at a point like B. This shape is the usual one for isoquants: They are bowed in, or convex. The reason isoquants have this shape is that as we move down the curve, we continue to substitute labor for capital. As the firm produces the same quantity of output using less capital, the additional labor it needs increases because of diminishing returns. Remember from the chapter that, as a consequence of diminishing returns, for a given decline in capital, increasing amounts of labor are necessary to produce the same level of output. Because the MRTS is equal to the change in capital divided by the change in labor, it will become smaller (in absolute value) as we move down an isoquant.

MyEconLab Concept Check

Marginal rate of technical substitution (MRTS) The rate at which a firm is able to substitute one input for another while keeping the level of output constant.

Isocost Lines

A firm wants to produce a given quantity of output at the lowest possible cost. We can show the relationship between the quantity of inputs used and the firm's total cost by using an *isocost* line. An **isocost line** shows all the combinations of two inputs, such as capital and labor, that have the same total cost.

Isocost line All the combinations of two inputs, such as capital and labor, that have the same total cost.

Graphing the Isocost Line

Suppose that Jill has \$6,000 per week to spend on capital and labor. Suppose, to simplify the analysis, that Jill can rent pizza ovens by the week. The table in Figure 11A.2 shows the combinations of capital and labor available to her if the rental price of ovens is \$1,000 per week and the wage rate is \$500 per week. The graph uses the data in the table to construct an isocost line. The isocost line intersects the vertical axis at the maximum number of ovens Jill can rent per week, which is shown by point A. The line intersects the horizontal axis at the maximum number of workers Jill can hire per week, which is point G. As Jill moves down the isocost line from point A, she gives up renting 1 oven for every 2 workers she hires. Any combination of inputs along the line or inside the line can be purchased with \$6,000. Any combination that lies outside the line cannot be purchased because it would have a total cost to Jill of more than \$6,000.

MyEconLab Concept Check

The Slope and Position of the Isocost Line

The slope of the isocost line is constant and equals the change in the quantity of ovens divided by the change in the quantity of workers. In this case, in moving from any point on the isocost line to any other point, the change in the quantity of ovens equals -1 , and the change in the quantity of workers equals 2 , so the slope equals $-1/2$. Notice that with a rental price of ovens of \$1,000 per week and a wage rate for labor of

Combinations of Workers and Ovens with a Total Cost of \$6,000			
Point	Ovens	Workers	Total Cost
A	6	0	$(6 \times \$1,000) + (0 \times \$500) = \$6,000$
B	5	2	$(5 \times \$1,000) + (2 \times \$500) = \$6,000$
C	4	4	$(4 \times \$1,000) + (4 \times \$500) = \$6,000$
D	3	6	$(3 \times \$1,000) + (6 \times \$500) = \$6,000$
E	2	8	$(2 \times \$1,000) + (8 \times \$500) = \$6,000$
F	1	10	$(1 \times \$1,000) + (10 \times \$500) = \$6,000$
G	0	12	$(0 \times \$1,000) + (12 \times \$500) = \$6,000$

MyEconLab Animation

Figure 11A.2

An Isocost Line

The isocost line shows the combinations of inputs with a total cost of \$6,000. The rental price of ovens is \$1,000 per week, so if Jill spends the whole \$6,000 on ovens, she can rent 6 ovens (point A). The wage rate is \$500 per week, so if Jill spends the whole \$6,000 on workers, she can hire 12 workers (point G). As she moves down the isocost line, she gives up renting 1 oven for every 2 workers she hires. Any combination of inputs along the line or inside the line can be purchased with \$6,000. Any combination that lies outside the line cannot be purchased with \$6,000.

\$500 per week, the slope of the isocost line is equal to the ratio of the wage rate divided by the rental price of capital, multiplied by -1 , or $-\$500/\$1,000 = -1/2$. In fact, this result will always hold, whatever inputs are involved and whatever their prices may be: *The slope of the isocost line is equal to the ratio of the price of the input on the horizontal axis divided by the price of the input on the vertical axis multiplied by -1 .*

The position of the isocost line depends on the level of total cost. Higher levels of total cost shift the isocost line outward, and lower levels of total cost shift the isocost line inward. This can be seen in Figure 11A.3, which shows isocost lines for total costs of \$3,000, \$6,000, and \$9,000. We have shown only three isocost lines in the graph, but there is, in fact, a different isocost line for each level of total cost.

The Position of the Isocost Line

The position of the isocost line depends on the level of total cost. As total cost increases from \$3,000 to \$6,000 to \$9,000 per week, the isocost line shifts outward. For each isocost line shown, the rental price of ovens is \$1,000 per week, and the wage rate is \$500 per week.

Figure 11A.4

Choosing Capital and Labor to Minimize Total Cost

Jill wants to produce 5,000 pizzas per week at the lowest total cost. Point B is the lowest-cost combination of inputs shown in the graph, but this combination of 1 oven and 4 workers will produce fewer than the 5,000 pizzas needed. Points C and D are combinations of ovens and workers that will produce 5,000 pizzas, but their total cost is \$9,000. The combination of 3 ovens and 6 workers at point A produces 5,000 pizzas at the lowest total cost of \$6,000.

Choosing the Cost-Minimizing Combination of Capital and Labor

Suppose Jill wants to produce 5,000 pizzas per week. Figure 11A.1 shows that there are many combinations of ovens and workers that will allow Jill to produce this level of output. There is only one combination of ovens and workers, however, that will allow her to produce 5,000 pizzas *at the lowest total cost*. Figure 11A.4 shows the isoquant $Q = 5,000$ along with three isocost lines. Point B is the lowest-cost combination of inputs shown in the graph, but this combination of 1 oven and 4 workers will produce fewer than the 5,000 pizzas needed. Points C and D are combinations of ovens and workers that will produce 5,000 pizzas, but their total cost is \$9,000. The combination of 3 ovens and 6 workers at point A produces 5,000 pizzas at the lowest total cost of \$6,000.

Figure 11A.4 shows that moving to an isocost line with a total cost of less than \$6,000 would mean producing fewer than 5,000 pizzas. Being at any point along the isoquant $Q = 5,000$ other than point A would increase total cost above \$6,000. In fact, the combination of inputs at point A is the only one on isoquant $Q = 5,000$ that has a total cost of \$6,000. All other input combinations on this isoquant have higher total costs. Notice also that at point A, the isoquant and the isocost lines are tangent, so the slope of the isoquant is equal to the slope of the isocost line at that point.

Different Input Price Ratios Lead to Different Input Choices

Jill's cost-minimizing choice of 3 ovens and 6 workers is determined jointly by these two factors:

1. The technology available to her, as represented by her firm's isoquants
2. Input prices, as represented by her firm's isocost lines

If the technology of making pizzas changes, perhaps because new ovens are developed, her isoquants will be affected, and her choice of inputs may change. If her isoquants remain unchanged but input prices change, then her choice of inputs may also change. This fact can explain why firms in different countries that face different input prices may produce the same good using different combinations of capital and labor, even though they have the same technology available.

MyEconLab Animation

Figure 11A.5

Changing Input Prices Affects the Cost-Minimizing Input Choice

As the graph shows, the input combination at point A, which was optimal for Jill, is not optimal for a businessperson in China. Using the input combination at point A would cost businesspeople in China more than \$6,000. Instead, the Chinese isocost line is tangent to the isoquant at point B, where the input combination is 2 ovens and 10 workers. Because ovens cost more in China but workers cost less, a Chinese firm will use fewer ovens and more workers than a U.S. firm, even if it has the same technology as the U.S. firm.

For example, suppose that in China, pizza ovens are higher priced and labor is lower priced than in the United States. In our example, Jill Johnson pays \$1,000 per week to rent pizza ovens and \$500 per week to hire workers. Suppose a businessperson in China must pay a price of \$1,500 per week to rent the identical pizza ovens but can hire Chinese workers who are as productive as U.S. workers at a wage of \$300 per week. Figure 11A.5 shows how the cost-minimizing input combination for the businessperson in China differs from Jill's.

Remember that the slope of the isocost line equals the wage rate divided by the rental price of capital multiplied by -1 . The slope of the isocost line that Jill and other U.S. firms face is $-\$500/\$1,000$, or $-1/2$. Firms in China, however, face an isocost line with a slope of $-\$300/\$1,500$, or $-1/5$. As Figure 11A.5 shows, the input combination at point A, which was optimal for Jill, is not optimal for a firm in China. Using the input combination at point A would cost a firm in China more than \$6,000. Instead, the Chinese isocost line is tangent to the isoquant at point B, where the input combination is 2 ovens and 10 workers. This result makes sense: Because ovens cost more in China but workers cost less, a Chinese firm will use fewer ovens and more workers than a U.S. firm, even if it has the same technology as the U.S. firm.

Solved Problem 11A.1

Firms Responding to Differences in Input Price Ratios

David Autor, an economist at MIT, has written that, “When Nissan Motor Company builds cars in Japan, it makes extensive use of industrial robots to reduce labor costs. When it assembles cars in India, it uses robots far more sparingly.”

Explain why Nissan uses this strategy. Illustrate your answer with an isoquant–isocost line graph.

Source: David Autor, “The ‘Task’ Approach to Labor Markets: An Overview,” *Journal of Labor Market Research*, Vol. 46, No. 3 (February 2013), pp. 185–199.

Solving the Problem

Step 1: Review the chapter material. This problem is about determining the optimal choice of inputs when input price ratios differ, so you may want to review the section “Different Input Price Ratios Lead to Different Input Choices,” which begins on page 454.

MyEconLab Interactive Animation

Step 2: Answer the question by explaining Nissan's strategy. Nissan must be pursuing this strategy because labor costs are higher in Japan than in India. The higher cost of labor relative to capital (industrial robots) in Japan means that Nissan faces an isocost line that is steeper in Japan than in India. Assuming that Nissan's technology is the same in the two countries, the steeper isocost line in Japan will be tangent to the isoquant at a point that represents more capital and less labor than in India. This conclusion is illustrated by the graph in step 3.

Step 3: Finish your answer by drawing a graph to illustrate your explanation in step 2. Nissan will produce in Japan at point A, using L_J units of labor and K_J units of capital. It will produce in India at point B, using L_I units of labor and K_I units of capital.

Another Look at Cost Minimization

We know that consumers maximize utility when they consume each good up to the point where the marginal utility per dollar spent is the same for every good. We can derive a very similar cost-minimization rule for firms. Remember that at the point of cost minimization, the isoquant and the isocost line are tangent, so they have the same slope. Therefore, *at the point of cost minimization, the marginal rate of technical substitution (MRTS) is equal to the wage rate divided by the rental price of capital.*

The slope of the isoquant tells us the rate at which a firm is able to substitute labor for capital, *keeping the level of output constant*. The slope of the isocost line tells us the rate at which a firm is able to substitute labor for capital, *given current input prices*. Only at the point of cost minimization are these two rates the same.

When we move from one point on an isoquant to another, we end up using more of one input and less of the other input, but the level of output remains the same. For example, as Jill moves down an isoquant, she uses fewer ovens and more workers but produces the same quantity of pizzas. In this chapter, we defined the *marginal product of labor* (MP_L) as the additional output produced by a firm as a result of hiring one more worker. Similarly, we can define the *marginal product of capital* (MP_K) as the additional output produced by a firm as a result of using one more machine. So, when Jill uses fewer ovens by moving down an isoquant, she loses output equal to:

$$-\text{Change in the quantity of ovens} \times MP_K.$$

But she uses more workers, so she gains output equal to:

$$\text{Change in the quantity of workers} \times MP_L.$$

We know that the gain in output from the additional workers is equal to the loss from the smaller quantity of ovens because total output remains the same along an isoquant. Therefore, we can write:

$$-\text{Change in the quantity of ovens} \times MP_K = \text{Change in the quantity of workers} \times MP_L.$$

Loss in output
from using fewer
ovens

Gain in output
from using more
workers

If we rearrange terms, we have the following:

$$\frac{-\text{Change in the quantity of ovens}}{\text{Change in the quantity of workers}} = \frac{MP_L}{MP_K}.$$

Because:

$$\frac{-\text{Change in the quantity of ovens}}{\text{Change in the quantity of workers}}$$

is the slope of the isoquant, it is equal to the marginal rate of technical substitution (multiplied by negative 1). So, we can write:

$$\frac{-\text{Change in the quantity of ovens}}{\text{Change in the quantity of workers}} = MRTS = \frac{MP_L}{MP_K}.$$

The slope of the isocost line equals the wage rate (w) divided by the rental price of capital (r). We saw earlier in this appendix that at the point of cost minimization, the MRTS equals the ratio of the prices of the two inputs. Therefore:

$$\frac{MP_L}{MP_K} = \frac{w}{r}.$$

We can rewrite this to show that at the point of cost minimization:

$$\frac{MP_L}{w} = \frac{MP_K}{r}.$$

This last expression tells us that to minimize cost for a given level of output, a firm should hire inputs up to the point where the last dollar spent on each input results in the same increase in output. If this equality did not hold, a firm could lower its costs by using more of one input and less of the other. For example, if the left side of the equation were greater than the right side, a firm could rent fewer ovens, hire more workers, and produce the same output at lower cost.

Determining the Optimal Combination of Inputs

Consider the information in the following table for Jill Johnson's restaurant:

Marginal product of capital	3,000 pizzas per oven
Marginal product of labor	1,200 pizzas per worker
Wage rate	\$300 per week
Rental price of ovens	\$600 per week

Briefly explain whether Jill is minimizing costs. If she is not minimizing costs, explain whether she should rent more ovens and hire fewer workers or rent fewer ovens and hire more workers.

Solving the Problem

Step 1: Review the chapter material. This problem is about determining the optimal choice of inputs by comparing the ratios of the marginal products of inputs to their prices, so you may want to review the section “Another Look at Cost Minimization,” which begins on page 456.

Step 2: Compute the ratios of marginal product to input price to determine whether Jill is minimizing costs. If Jill is minimizing costs, the following relationship should hold:

$$\frac{MP_L}{w} = \frac{MP_K}{r}$$

In this case, we have:

$$MP_L = 1,200$$

$$MP_K = 3,000$$

$$w = \$300$$

$$r = \$600.$$

So:

$$\frac{MP_L}{w} = \frac{1,200}{\$300} = 4 \text{ pizzas per dollar, and } \frac{MP_K}{r} = \frac{3,000}{\$600} = 5 \text{ pizzas per dollar.}$$

Because the two ratios are not equal, Jill is not minimizing cost.

Step 3: Determine how Jill should change the mix of inputs she uses. Jill produces more pizzas per dollar from the last oven than from the last worker. This indicates that she has too many workers and too few ovens. Therefore, to minimize cost, Jill should use more ovens and hire fewer workers.

Making the Connection

MyEconLab Video

Do National Football League Teams Behave Efficiently?

In the National Football League (NFL), the “salary cap” is the maximum amount each team can spend in a year on salaries for football players. Each year’s salary cap results from negotiations between the league and the union representing the players. To achieve efficiency, an NFL team should distribute salaries among players so as to maximize the level of output—in this case, winning football games—given the constant level of cost represented by the salary cap. (Notice that maximizing the level of output for a given level of cost is equivalent to minimizing cost for a given level of output. To see why, think about the situation in which an isocost line is tangent to an isoquant. At the point of tangency, the firm has simultaneously minimized the cost of producing the level of output represented by the isoquant and maximized the output produced at the level of cost represented by the isocost line.)

In distributing the fixed amount of salary payments available, teams should equalize the ratios of the marginal productivity of players, as represented by their contribution to winning games, to the salaries players receive. Just as a firm may not use a machine that has a very high marginal product if its rental price is very high, a football team may not want to hire a superstar player if the salary the team would need to pay is too high.

Did a rule change keep Tampa Bay from paying Jameis Winston too much?

Economists Cade Massey, of the University of Pennsylvania, and Richard Thaler, of the University of Chicago, have analyzed whether NFL teams distribute their salaries efficiently. NFL teams obtain their players either by signing free agents—who are players whose contracts with other teams have expired—or by signing players chosen in the annual draft of eligible college players. The college draft consists of seven rounds, with the teams with the worst records the previous year choosing first. Massey and Thaler find that, in fact, NFL teams do not allocate salaries efficiently. In particular, the players chosen with the first few picks of the first round of the draft tend to be paid salaries that are much higher relative to their marginal products than are players taken later in the first round. A typical team with a high draft pick would increase its ability to win football games at the constant cost represented by the salary cap if it traded for lower draft picks, providing it could find another team willing to make the trade. Why do NFL teams apparently make the error of not efficiently distributing salaries? Massey and Thaler argue that general managers of NFL teams tend to be overconfident in their ability to forecast how well a college player is likely to perform in the NFL.

General managers of NFL teams are not alone in suffering from overconfidence. Studies have shown that, in general, people tend to overestimate their ability to forecast an uncertain outcome. Because NFL teams tend to overestimate the future marginal productivity of high draft picks, they pay them salaries that are inefficiently high compared to salaries other draft picks receive. NFL teams were aware that they were probably overpaying high draft picks. In 2011, they negotiated a new contract with the NFL Players Union that limited the salaries that drafted players could receive.

This example shows that the concepts developed in this chapter provide powerful tools for analyzing whether firms are operating efficiently.

The Expansion Path

We can use isoquants and isocost lines to examine what happens as a firm expands its level of output. Figure 11A.6 shows three isoquants for a firm that produces bookcases. The isocost lines are drawn under the assumption that the machines used in producing bookcases can be rented for \$100 per day and the wage rate is \$25 per day. The point where each isoquant is tangent to an isocost line determines the cost-minimizing combination of capital and labor for producing that level of output. For example, 10 machines and 40 workers is the cost-minimizing combination of inputs for producing 50 bookcases per day. The cost-minimizing points A, B, and C lie along the firm’s **expansion path**, which is a curve that shows the cost-minimizing combination of inputs for every level of output.

An important point to note is that the expansion path represents the least-cost combination of inputs to produce a given level of output *in the long run*, when the firm is able to vary the levels of all of its inputs. We know, though, that in the short run, at least one input is fixed. We can use Figure 11A.6 to show that as the firm expands in the short run, its costs will be higher than in the long run. Suppose that the firm is currently at point B, using 15 machines and 60 workers to produce 75 bookcases per day. The firm wants to expand its output to 100 bookcases per day, but in the short run, it is unable to increase the quantity of machines it uses. Therefore, to expand output, it must hire more workers. The figure shows that in the short run, to produce 100 bookcases per day using 15 machines, the lowest costs it can attain are at point D, where it employs 110 workers. With a rental price of machines of \$100 per day and a wage rate of \$25 per day, in the short run, the firm will have total costs

Expansion path A curve that shows a firm’s cost-minimizing combination of inputs for every level of output.

MyEconLab Animation

Figure 11A.6 The Expansion Path

The tangency points A, B, and C lie along the firm's expansion path, which is a curve that shows the cost-minimizing combination of inputs for every level of output. In the short run, when the quantity of machines is fixed, the firm can expand output from 75 bookcases per day to 100 bookcases per day at the lowest cost only

by moving from point B to point D and increasing the number of workers from 60 to 110. In the long run, when it can increase the quantity of machines it uses, the firm can move from point D to point C, thereby reducing its total costs of producing 100 bookcases per day from \$4,250 to \$4,000.

of \$4,250 to produce 100 bookcases per day. In the long run, though, the firm can increase the number of machines it uses from 15 to 20 and reduce the number of workers from 110 to 80. This change allows it to move from point D to point C on its expansion path and to lower its total costs of producing 100 bookcases per day from \$4,250 to \$4,000. The firm's minimum total costs of production are lower in the long run than in the short run.

11A.6 (Related to Solved Problem 11A.1 on page 455) India has less arable land per farmer than the United States. As a result, the price of labor in India is less relative to the price of land than it is in the United States. Assume that United States and India had access to the same technology for producing grains. Use an isoquant-isocost graph to illustrate why the combination of land and labor for producing grains in India would have been different from the combination used to produce grains in the United States.

11A.7 (Related to Solved Problem 11A.2 on page 457) Consider the information in the following table for Jill Johnson's restaurant:

Marginal product of capital	4,000
Marginal product of labor	100
Wage rate	\$10
Rental price of pizza ovens	\$500

Briefly explain whether Jill is minimizing costs. If she is not minimizing costs, explain whether she should rent more ovens and hire fewer workers or rent fewer ovens and hire more workers.

11A.8 (Related to Solved Problem 11A.2 on page 457) Draw an isoquant-isocost line graph to illustrate the following situation: Jill Johnson can rent pizza ovens for \$200 per week and hire workers for \$100 per

week. Currently, she is using 5 ovens and 10 workers to produce 20,000 pizzas per week and has total costs of \$2,000. Jill's marginal rate of technical substitution (MRTS) equals -1 . Explain why this means that she's not minimizing costs and what she could do to minimize costs.

11A.9 Draw an isoquant-isocost line graph to illustrate the following situation and the change that occurs: Jill Johnson can rent pizza ovens for \$2,000 per week and hire workers for \$1,000 per week. Currently, she is using 5 ovens and 10 workers to produce 20,000 pizzas per week and has total costs of \$20,000. Then Jill reorganizes the way things are done in her business and achieves positive technological change.

11A.10 Use the following graph to answer the following questions about Jill Johnson's isoquant curve.

- Which combination of inputs yields more output: combination A (3 ovens and 2 workers) or combination B (2 ovens and 3 workers)?
- What will determine whether Jill selects A, B, or some other point along this isoquant curve?
- Is the marginal rate of technical substitution (MRTS) greater at point A or point B?

11A.11 A company sells eggs for \$1,000 per week and hire workers at \$500 per week. Are Cage-Free Eggs the Road to Riches?

In recent years, the demand for healthier foods has increased. In addition, many people are concerned that some animals being raised for food are not being treated humanely. There are more than 65,000 poultry farms in the United States that specialize in producing eggs. Most farmers raise chickens in cages that restrict their movement. Some farmers, though, have begun selling eggs produced using “cage-free” or “free-range” methods. Although the U.S. Department of Agriculture has not developed official definitions of these terms, chickens raised this way have significant room to move around, and some are raised outdoors.

Some consumers are willing to pay more for eggs produced by cage-free chickens. An article in the *Wall Street Journal* quoted one consumer’s reason for buying cage-free eggs: “I like my chickens able to eat bugs and scratch.” Costs of raising chickens this way are higher because fewer chickens can be raised in an area of a given size, the chickens eat more because they are moving around, and some chickens die from being pecked by other chickens. Some farmers, though, can sell cage-free eggs for as much as double the price of eggs produced using conventional methods. Overall, farmers have been earning higher profits on cage-free eggs than on conventionally produced eggs.

As of 2015, only about 6 percent of eggs were produced by cage-free chickens. But many farmers were switching to this method. One farmer gave this explanation, “Farming is about making a profit, and if someone is willing to pay us extra, we’re going to do that.” But how much longer would these profits continue? Although the share of cage-free eggs was small, it was growing rapidly, and as more farmers switched to these methods, there was already an indication that the premium over the prices of conventional eggs was shrinking.

The process of new firms entering a profitable market and driving down prices and profits is not found only in agriculture. Throughout the economy, entrepreneurs are continually introducing new products or new ways of selling products, which—when successful—enable them to earn economic profits in the short run. But in the long run, competition among firms forces prices to the level where they just cover the costs of production. This process of competition is at the heart of the market system and is the focus of this chapter.

Economics in Your Life

Are You an Entrepreneur?

Were you an entrepreneur during high school? You may have worked as a babysitter or mowed lawns for your neighbors. While you may not think of these jobs as being small businesses, that is exactly what they are. How did you decide what price to charge for your services? You may have wanted to charge \$25 per hour for babysitting or mowing lawns, but you probably charged much less. As you read the chapter, think about the competitive situation you faced as a teenage entrepreneur and try to determine why the prices received by most people who babysit and mow lawns are so low. You can check your answers against those we provide on **page 490** at the end of this chapter.

An *industry* refers to all the firms selling a particular good or service—for instance, eggs, automobiles, or life insurance. Poultry farming is an example of a *perfectly competitive* industry. Firms in these industries are unable to control the prices of the products they sell and are unable to earn an economic profit in the long run for two main reasons:

1. Firms in these industries sell identical products.
2. It is easy for new firms to enter these industries.

Studying how perfectly competitive industries operate is the best way to understand how markets answer the fundamental economic questions discussed in Chapter 1:

- What goods and services will be produced?
- How will the goods and services be produced?
- Who will receive the goods and services produced?

Most industries, though, are not perfectly competitive. In most industries, firms do *not* produce identical products. And in some industries, it may be difficult for new firms to enter. There are thousands of industries in the United States. Although in some ways each industry is unique, industries share enough similarities that economists can group them into four market structures. In particular, any industry has three key characteristics:

1. The number of firms in the industry
2. The similarity of the good or service produced by the firms in the industry
3. The ease with which new firms can enter the industry

Economists use these characteristics to classify industries into the four market structures listed in Table 12.1.

Many industries, including restaurants, clothing stores, and other retailers, have a large number of firms selling products that are differentiated, rather than identical, and fall into the category of *monopolistic competition*. Some industries, such as computers and automobiles, have only a few firms and are *oligopolies*. Finally, a few industries, such as the delivery of first-class mail by the U.S. Postal Service, have only one firm and are *monopolies*. After discussing perfect competition in this chapter, we will devote a chapter to each of these other market structures.

12.1

Perfectly Competitive Markets

LEARNING OBJECTIVE: Explain what a perfectly competitive market is and why a perfect competitor faces a horizontal demand curve.

Why are firms in a **perfectly competitive market** unable to control the prices of the goods they sell, and why are the owners of these firms unable to earn economic profits in the long run? We can begin our analysis by listing the three conditions that make a market perfectly competitive:

1. There must be many buyers and many firms, all of which are small relative to the market.
2. All firms in the market must sell identical products.
3. There must be no barriers to new firms entering the market.

All three of these conditions hold in markets for agricultural products. For example, no single consumer or producer of apples buys or sells more than a tiny fraction of the total apple crop. The apples sold by each apple grower are identical, and there are no barriers to a new firm entering this market by purchasing land and planting apple trees. As we will see, it is the existence of many firms, all selling the same good, that keeps any single apple farmer from affecting the price of apples.

Although the market for apples meets the conditions for perfect competition, the markets for most goods and services do not. In particular, the second and third conditions are very restrictive. In most markets that have many buyers and sellers, firms do not sell identical products. For example, not all restaurant meals are the same, nor is all women's clothing the same. In later chapters, we will explore the common situation of monopolistic competition where many firms are selling similar but not identical products, and we will analyze industries that are oligopolies, where entry of new firms is difficult, and industries that are monopolies, where entry of new firms is impossible. In this chapter, we concentrate on perfectly competitive markets so we can use them as a benchmark to analyze how firms behave when they face the maximum possible competition.

A Perfectly Competitive Firm Cannot Affect the Market Price

Prices in perfectly competitive markets are determined by the interaction of demand and supply for the good or service. The actions of any single consumer or any single firm have no effect on the market price. Consumers and firms have to accept the market price if they want to buy and sell in a perfectly competitive market.

Because a firm in a perfectly competitive market is very small relative to the market and because it is selling exactly the same product as every other firm, it can sell as much as it wants without having to lower its price. If a perfectly competitive firm tries to raise its price, it won't sell anything at all because consumers will switch to buying the product from the firm's competitors. Therefore, the firm will be a **price taker** and will have to charge the same price as every other firm in the market. Although we don't usually think of firms as being too small to affect the market price, consumers are often in the position of being price takers. For instance, suppose your local supermarket is selling bread for \$2.50 per loaf. You can load up your shopping cart with 20 loaves of bread, and the supermarket will gladly sell them all to you for \$2.50 per loaf. But if you go to the cashier and offer to buy the bread for \$2.49 per loaf, he or she will not sell it to you at that price. As a buyer, you are too small relative to the bread market to have any effect on the equilibrium price. Whether you leave the supermarket and buy no bread or you buy 20 loaves, you are unable to change the market price of bread by even one cent.

The situation you face as a bread buyer is the same one a wheat farmer faces as a wheat seller. There are about 150,000 farmers growing wheat in the United States. The market price of wheat is determined not by any individual wheat farmer but by the interaction of all the buyers and all the sellers in the wheat market. If any one wheat farmer has the best crop the farmer has ever had, or if any one wheat farmer stops growing wheat altogether, the market price of wheat will not be affected *because the market supply curve for wheat will not shift enough to change the equilibrium price by even one cent.*

Figure 12.1 A Perfectly Competitive Firm Faces a Horizontal Demand Curve

A firm in a perfectly competitive market is selling exactly the same product as all of the other firms in the market. Therefore, it can sell as much as it wants at the current market price, but it cannot sell anything at all if it raises the price by even 1 cent. As

a result, the demand curve for a perfectly competitive firm's output is a horizontal line. In the figure, whether the wheat farmer sells 6,000 bushels or 15,000 bushels per year has no effect on the market price of \$7.

The Demand Curve for the Output of a Perfectly Competitive Firm

Suppose Bill Parker grows wheat on a 250-acre farm in Washington State. Farmer Parker is selling wheat in a perfectly competitive market, so he is a price taker. Because he can sell as much wheat as he chooses at the market price—but can't sell any wheat at all at a higher price—the demand curve for his wheat has an unusual shape: It is horizontal, as shown in Figure 12.1. With a horizontal demand curve, Farmer Parker must accept the market price, which in this case is \$7 per bushel. Whether Farmer Parker sells 6,000 bushels per year or 15,000 has no effect on the market price.

Don't Let This Happen to You

Don't Confuse the Demand Curve for Farmer Parker's Wheat with the Market Demand Curve for Wheat

The demand curve for wheat has the normal downward-sloping shape. If the price of wheat goes up, the quantity of wheat demanded goes down, and if the price of wheat goes down, the quantity of wheat demanded goes up. But the demand curve for the output of a single wheat farmer is *not* downward sloping: It is a horizontal line. If an individual wheat farmer tries to increase the price he charges for his wheat, the quantity demanded falls to zero because buyers will purchase from one of the other 150,000 wheat farmers. But any one farmer can sell as much wheat as the farmer can produce without needing to cut the price. Both of these features of this market hold because each

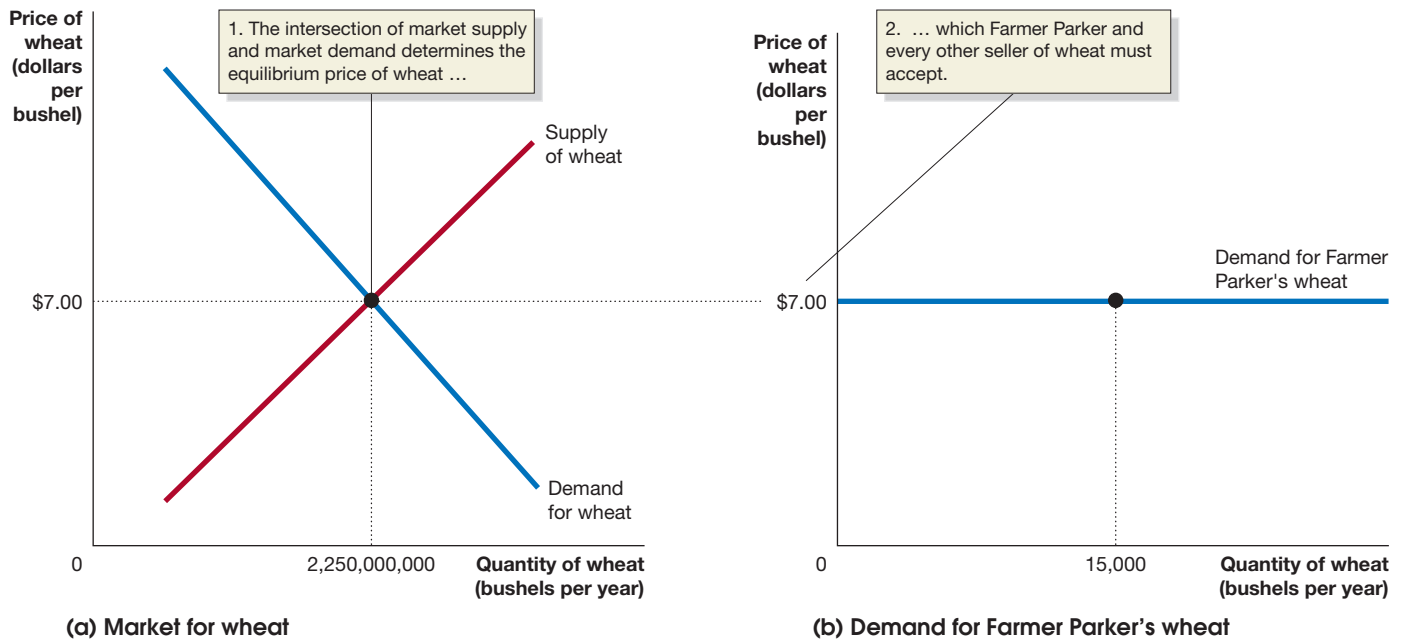

wheat farmer is very small relative to the overall market for wheat.

When we draw graphs of the wheat market, we usually show the market equilibrium quantity in millions or billions of bushels. When we draw graphs of the demand for wheat produced by one farmer, we usually show the quantity produced in smaller units, such as thousands of bushels. It is important to remember this difference in scale when interpreting these graphs.

Finally, it is not just wheat farmers who have horizontal demand curves for their products; any firm in a perfectly competitive market faces a horizontal demand curve.

Figure 12.2 The Market Demand for Wheat versus the Demand for One Farmer's Wheat

In a perfectly competitive market, price is determined by the intersection of market demand and market supply. In panel (a), the demand and supply curves for wheat intersect at a price of \$7 per bushel. An individual wheat farmer like Farmer Parker cannot affect the market price for wheat. Therefore, as panel (b) shows, the demand curve for Farmer Parker's wheat is a

horizontal line. To understand this figure, it is important to notice that the scales on the horizontal axes in the two panels are very different. In panel (a), the equilibrium quantity of wheat is 2.25 billion bushels, and in panel (b), Farmer Parker is producing only 15,000 bushels of wheat.

The demand curve for Farmer Parker's wheat is very different from the market demand curve for wheat. Panel (a) of Figure 12.2 shows the market for wheat. The demand curve in panel (a) is the *market demand curve for wheat* and has the normal downward slope we are familiar with from the market demand curves in Chapter 3. Panel (b) of Figure 12.2 shows the demand curve for Farmer Parker's wheat, which is a horizontal line. By viewing these graphs side by side, you can see that the price Farmer Parker receives for his wheat in panel (b) is determined by the interaction of all sellers and all buyers of wheat in the wheat market in panel (a). Notice, however, that the scales on the horizontal axes in the two panels are very different. In panel (a), the equilibrium quantity of wheat is 2.25 billion bushels. In panel (b), Farmer Parker is producing only 15,000 bushels, or less than 0.001 percent of market output. We need to use different scales in the two panels so we can display both of them on one page. Keep in mind this key point: Farmer Parker's output of wheat is very small relative to the total market output.

12.2 How a Firm Maximizes Profit in a Perfectly Competitive Market

LEARNING OBJECTIVE: Explain how a firm maximizes profit in a perfectly competitive market.

We have seen that Farmer Parker cannot control the price of his wheat. In this situation, how does he decide how much wheat to produce? We assume that Farmer Parker's objective is to maximize profit. This assumption is reasonable for most firms, most of the time. Remember that **profit** is the difference between total revenue (TR) and total cost (TC):

$$\text{Profit} = TR - TC.$$

To maximize his profit, Farmer Parker should produce the quantity of wheat where the difference between the total revenue he receives and his total cost is as large as possible.

Profit Total revenue minus total cost.

Revenue for a Firm in a Perfectly Competitive Market

To understand how Farmer Parker maximizes profit, let's first consider his revenue. To keep the numbers simple, we will assume that he owns a very small farm and produces at most 10 bushels of wheat per year. Table 12.2 shows the revenue Farmer Parker will earn from selling various quantities of wheat if the market price for wheat is \$7.

The third column in Table 12.2 shows that Farmer Parker's *total revenue* rises by \$7 for every additional bushel he sells because he can sell as many bushels as he wants at the market price of \$7 per bushel. The fourth and fifth columns in the table show Farmer Parker's *average revenue* and *marginal revenue* from selling wheat. His **average revenue (AR)** equals his total revenue divided by the quantity of bushels he sells. For example, if he sells 5 bushels for a total of \$35, his average revenue is $\$35/5 = \7 . Notice that his average revenue is also equal to the market price of \$7. In fact, for any level of output, a firm's average revenue is always equal to the market price. This equality holds because total revenue equals price times quantity ($TR = P \times Q$), and average revenue equals total revenue divided by quantity ($AR = TR/Q$). So, $AR = TR/Q = (P \times Q)/Q = P$.

Farmer Parker's **marginal revenue (MR)** is the change in his total revenue from selling one more bushel:

$$\text{Marginal revenue} = \frac{\text{Change in total revenue}}{\text{Change in quantity}}, \text{ or } MR = \frac{\Delta TR}{\Delta Q}.$$

Each additional bushel Farmer Parker sells always adds \$7 to his total revenue, so his marginal revenue is \$7. Farmer Parker's marginal revenue is \$7 per bushel because he is selling wheat in a perfectly competitive market and can sell as much as he wants at the market price. In fact, Farmer Parker's marginal revenue and average revenue are both equal to the market price. This is an important point: *For a firm in a perfectly competitive market, price is equal to both average revenue and marginal revenue.* MyEconLab Concept Check

Determining the Profit-Maximizing Level of Output

To determine how Farmer Parker can maximize profit, we have to consider his costs as well as his revenue. A wheat farmer has many costs, including the costs of seed and fertilizer, as well as the wages of farm workers. In Table 12.3, we bring together the revenue data from Table 12.2 with cost data for Farmer Parker's farm. Recall that a firm's *marginal cost* is the increase in total cost resulting from producing another unit of output.

We calculate profit in the fourth column by subtracting total cost in the third column from total revenue in the second column. The fourth column shows that as long as Farmer Parker produces between 3 and 9 bushels of wheat, he will earn a profit.

Average revenue (AR) Total revenue divided by the quantity of the product sold.

Marginal revenue (MR) The change in total revenue from selling one more unit of a product.

10	70.00	72.00	-2.00	7.00	15.50

Table 12.3

Farmer Parker's Profit from Wheat Farming

His maximum profit is \$13.50, which he will earn by producing 7 bushels of wheat. Because Farmer Parker wants to maximize his profit, we would expect him to produce 7 bushels of wheat. Producing more than 7 bushels reduces his profit. For example, if he produces 8 bushels of wheat, his profit will decline from \$13.50 to \$11.50. The values for marginal cost given in the last column of the table help us understand why Farmer Parker's profits will decline if he produces more than 7 bushels of wheat: After the seventh bushel of wheat, rising marginal cost causes Farmer Parker's profits to decline.

In fact, comparing the marginal cost and marginal revenue at each level of output is an alternative method of calculating Farmer Parker's profit. We illustrate the two methods of calculating profit in Figure 12.3. We show the total revenue and total cost

(a) Total revenue, total cost, and profit

(b) Marginal revenue and marginal cost

MyEconLab Animation

Figure 12.3 The Profit-Maximizing Level of Output

In panel (a), Farmer Parker maximizes his profit where the positive vertical distance between total revenue and total cost is the largest, which occurs at an output of 7 bushels. Panel (b) shows that Farmer Parker's marginal revenue (MR) is equal to a constant \$7 per bushel. He maximizes profit by producing wheat up to the point where the marginal revenue of the last bushel produced is equal to its marginal cost, or $MR = MC$. In this case, at no level

of output does marginal revenue exactly equal marginal cost. The closest Farmer Parker can come is to produce 7 bushels of wheat. He will not want to continue to produce once marginal cost is greater than marginal revenue because that would reduce his profits. Panels (a) and (b) show alternative ways of thinking about how Farmer Parker can determine the profit-maximizing quantity of wheat to produce.

approach in panel (a) and the marginal revenue and marginal cost approach in panel (b). Total revenue is a straight line on the graph in panel (a) because total revenue increases at a constant rate of \$7 for each additional bushel sold. Farmer Parker's profit is maximized when the vertical distance between the line representing total revenue and the total cost curve is as large as possible. Just as we saw in Table 12.3, his maximum profit occurs at an output of 7 bushels.

The last two columns of Table 12.3 show the marginal revenue (MR) Farmer Parker receives from selling another bushel of wheat and his marginal cost (MC) of producing another bushel of wheat. Panel (b) of Figure 12.3 shows Farmer Parker's marginal revenue and marginal cost. Because marginal revenue is always equal to \$7, it is a horizontal line at the market price. We have already seen that the demand curve for a perfectly competitive firm is also a horizontal line at the market price. *Therefore, the marginal revenue curve for a perfectly competitive firm is the same as its demand curve.* Farmer Parker's marginal cost of producing wheat first falls and then rises, following the usual pattern we discussed in the previous chapter.

We know from panel (a) that profit is at a maximum at 7 bushels of wheat. In panel (b), profit is also at a maximum at 7 bushels of wheat. To understand why profit is maximized at the level of output where marginal revenue equals marginal cost, remember a key economic principle: *Optimal decisions are made at the margin.* Firms use this principle to decide the quantity of a good to produce. For example, in deciding how much wheat to produce, Farmer Parker needs to compare the marginal revenue he earns from selling another bushel of wheat to the marginal cost of producing that bushel. The difference between the marginal revenue and the marginal cost is the additional profit (or loss) from producing one more bushel. As long as marginal revenue is greater than marginal cost, Farmer Parker's profits are increasing, and he will want to expand production. For example, he will not stop producing at 6 bushels of wheat because producing and selling the seventh bushel adds \$7.00 to his revenue but only \$6.50 to his cost, so his profit increases by \$0.50. He wants to continue producing until the marginal revenue he receives from selling another bushel is equal to the marginal cost of producing it. At that level of output, he will make no *additional* profit by selling another bushel, so he will have maximized his profit.

By inspecting Table 12.3, we can see that there is no level of output at which marginal revenue exactly equals marginal cost. The closest Farmer Parker can come is to produce 7 bushels of wheat. He will not want to produce additional wheat once marginal cost is greater than marginal revenue because that would reduce his profits. For example, the eighth bushel of wheat adds \$9.00 to his cost but only \$7.00 to his revenue, so producing the eighth bushel *reduces* his profit by \$2.00.

From the information in Table 12.3 and Figure 12.3, we can draw the following conclusions:

1. The profit-maximizing level of output is where the positive difference between total revenue and total cost is the greatest.
2. The profit-maximizing level of output is also where marginal revenue equals marginal cost, or $MR = MC$.

Both of these conclusions are true for any firm, whether or not it is in a perfectly competitive industry. We can draw one other conclusion about profit maximization that is true only of firms in perfectly competitive industries: For a firm in a perfectly competitive industry, price is equal to marginal revenue, or $P = MR$. So we can restate the $MR = MC$ condition as $P = MC$.

Illustrating Profit or Loss on the Cost Curve Graph

LEARNING OBJECTIVE: Use graphs to show a firm's profit or loss.

We have seen that profit is the difference between total revenue and total cost. We can also express profit in terms of *average total cost* (ATC). This approach allows us to show profit on the cost curve graph we developed in the last chapter.

MyEconLab Animation

Figure 12.4 The Area of Maximum Profit

A firm maximizes profit at the level of output at which marginal revenue equals marginal cost. The difference between price and average total cost equals profit per unit of output. Total profit equals

profit per unit multiplied by the number of units produced. Total profit is represented by the area of the green-shaded rectangle, which has a height equal to $(P - ATC)$ and a width equal to Q .

To begin, we need to work through several steps to determine the relationship between profit and average total cost. Because profit is equal to total revenue (TR) minus total cost (TC) and total revenue is price times quantity, we can write the following:

$$\text{Profit} = (P \times Q) - TC.$$

If we divide both sides of this equation by Q , we have:

$$\frac{\text{Profit}}{Q} = \frac{(P \times Q)}{Q} - \frac{TC}{Q},$$

or:

$$\frac{\text{Profit}}{Q} = P - ATC,$$

because TC/Q equals ATC . This equation tells us that profit per unit (or average profit) equals price minus average total cost. Finally, we obtain the equation for the relationship between total profit and average total cost by multiplying by Q :

$$\text{Profit} = (P - ATC) \times Q.$$

This equation tells us that a firm's total profit is equal to the difference between price and average total cost multiplied by the quantity produced.

Showing Profit on a Graph

Figure 12.4 shows the relationship between a firm's average total cost and its marginal cost that we discussed in the last chapter. In this figure, we also show the firm's marginal revenue curve (which is the same as its demand curve) and the area representing total profit. Using the relationship between profit and average total cost that we just determined, we can say that the area representing total profit has a height equal to $(P - ATC)$ and a base equal to Q . This area is shown by the green-shaded rectangle.

Solved Problem 12.3

MyEconLab Interactive Animation

Determining Profit-Maximizing Price and Quantity

Suppose that Andy sells basketballs in the perfectly competitive basketball market. His output per day and his costs are as follows:

Output per Day	Total Cost
0	\$10.00
1	20.50
2	24.50
3	28.00
4	34.00
5	43.00
6	55.50
7	72.00
8	93.00
9	119.00

- Suppose the current equilibrium price in the basketball market is \$12.50. To maximize profit, how many basketballs will Andy produce, what price will he charge, and how much profit (or loss) will he earn? Draw a graph to illustrate your answer. Your graph should be labeled clearly and should include Andy's demand, ATC, AVC, MC, and MR curves; the price he is charging; the quantity he is producing; and the area representing his profit (or loss).
- Suppose the equilibrium price of basketballs falls to \$6.00. Now how many basketballs will Andy produce, what price will he charge, and how much profit (or loss) will he make? Draw a graph to illustrate this situation, using the instructions in part (a).

Solving the Problem

Step 1: Review the chapter material. This problem is about using cost curve graphs to analyze perfectly competitive firms, so you may want to review the section "Illustrating Profit or Loss on the Cost Curve Graph," which begins on page 472.

Step 2: Calculate Andy's marginal cost, average total cost, and average variable cost. To maximize profit, Andy will produce the level of output where marginal revenue is equal to marginal cost. We can calculate marginal cost from the information given in the following table. We can also calculate average total cost and average variable cost in order to draw the required graph. Average total cost (ATC) equals total cost (TC) divided by the level of output (Q). Average variable cost (AVC) equals variable cost (VC) divided by output (Q). To calculate variable cost, recall that total cost equals variable cost plus fixed cost. When output equals zero, total cost equals fixed cost. In this case, fixed cost equals \$10.00.

Output per Day (Q)	Total Cost (TC)	Fixed Cost (FC)	Variable Cost (VC)	Average Total Cost (ATC)	Average Variable Cost (AVC)	Marginal Cost (MC)
0	\$10.00	\$10.00	\$0.00	—	—	—
1	20.50	10.00	10.50	\$20.50	\$10.50	\$10.50
2	24.50	10.00	14.50	12.25	7.25	4.00
3	28.00	10.00	18.00	9.33	6.00	3.50
4	34.00	10.00	24.00	8.50	6.00	6.00
5	43.00	10.00	33.00	8.60	6.60	9.00
6	55.50	10.00	45.50	9.25	7.58	12.50
7	72.00	10.00	62.00	10.29	8.86	16.50
8	93.00	10.00	83.00	11.63	10.38	21.00
9	119.00	10.00	109.00	13.22	12.11	26.00

Step 3: Use the information from the table in step 2 to calculate how many basketballs Andy will produce, what price he will charge, and how much profit he will earn if the market price of basketballs is \$12.50. Andy's marginal revenue is equal to the market price of \$12.50. Marginal revenue equals marginal cost when Andy produces 6 basketballs per day. So, Andy will produce 6 basketballs per day and charge a price of \$12.50 per basketball. Andy's profit is equal to his total revenue minus his total costs. His total revenue equals the 6 basketballs he sells multiplied by the \$12.50 price, or \$75.00. So, his profit equals $\$75.00 - \$55.50 = \$19.50$.

Step 4: Use the information from the table in step 2 to illustrate your answer to part (a) with a graph.

Step 5: Calculate how many basketballs Andy will produce, what price he will charge, and how much profit he will earn when the market price of basketballs is \$6.00. Referring to the table in step 2, we can see that marginal revenue equals marginal cost when Andy produces 4 basketballs per day. He charges the market price of \$6.00 per basketball. His total revenue is only \$24.00, while his total costs are \$34.00, so he will have a loss of \$10.00. (Can we be sure that Andy will continue to produce even though he is operating at a loss? We answer this question in the next section.)

Step 6: Illustrate your answer to part (b) with a graph.

Your Turn: For more practice, do related problems 3.3 and 3.4 on pages 493–436 at the end of this chapter.

Don't Let This Happen to You

Remember That Firms Maximize Their Total Profit, Not Their Profit per Unit

A student examines the following graph and argues: "I think that a firm will want to produce at Q_1 , not Q_2 . At Q_1 , the distance between price and average total cost is the greatest. So at Q_1 , the firm will be maximizing its profit per unit." Briefly explain whether you agree with the student's argument.

The student's argument is incorrect because firms are interested in maximizing their *total* profit, not their profit per unit. We know that profit is not maximized at Q_1 because at that level of output, marginal revenue is greater than marginal cost. A firm can always increase its profit by producing any unit that adds more to its revenue than it does to its costs. Only when the firm has expanded production to Q_2 will it have produced every unit for which marginal revenue is greater than marginal cost. At that level of output, it will have maximized profit.

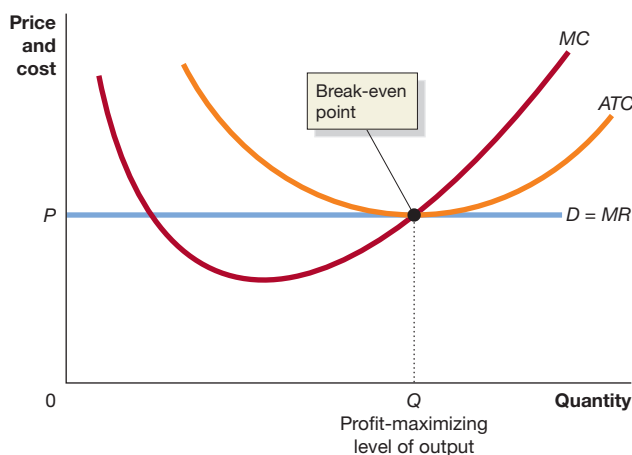

MyEconLab Study Plan

Your Turn: Test your understanding by doing related problem 3.5 on page 494 at the end of this chapter.

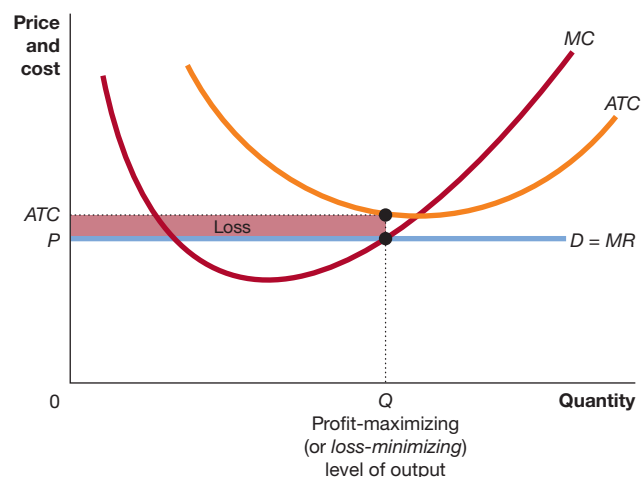

Illustrating When a Firm Is Breaking Even or Operating at a Loss

We have already seen that to maximize profit, a firm produces the level of output where marginal revenue equals marginal cost. But will the firm actually make a profit at that level of output? It depends on the relationship of price to average total cost. There are three possibilities:

1. $P > ATC$, which means the firm makes a profit.
2. $P = ATC$, which means the firm *breaks even* (its total cost equals its total revenue).
3. $P < ATC$, which means the firm experiences a loss.

(a) A firm breaking even

(b) A firm experiencing a loss

MyEconLab Animation

Figure 12.5 A Firm Breaking Even and a Firm Experiencing a Loss

In panel (a), price equals average total cost, and the firm breaks even because its total revenue will be equal to its total cost. In this situation, the firm makes zero economic profit. In panel (b), price is below average total

cost, and the firm experiences a loss. The loss is represented by the area of the red-shaded rectangle, which has a height equal to $(ATC - P)$ and a width equal to Q .

Figure 12.4 on page 473 shows the first possibility, where the firm makes a profit. Panels (a) and (b) of Figure 12.5 show the situations where a firm breaks even or suffers a loss. In panel (a) of Figure 12.5, at the level of output at which $MR = MC$, price is equal to average total cost. Therefore, total revenue is equal to total cost, and the firm will break even, making zero economic profit. In panel (b), at the level of output at which $MR = MC$, price is less than average total cost. Therefore, total revenue is less than total cost, and the firm suffers a loss. In this case, maximizing profit amounts to *minimizing* loss.

Losing Money in the Solar Panel Industry

In a market system, a good or service becomes available to consumers only if an entrepreneur brings the product to market. Thousands of new businesses open every week in the United States. Each new business represents an entrepreneur risking his or her funds to earn a profit. Of course, there are no guarantees of success, and many new businesses experience losses rather than earn the profits their owners hoped for.

By the mid-2000s, high oil prices and concern over the pollution caused by burning fossil fuels led more people to become interested in solar energy. Technological advances reduced the cost of solar photovoltaic cells used in solar panels. In addition, households installing a solar energy system could receive a federal tax credit equal to 30 percent of the cost of the system. For several years, falling production costs and increased demand led entrepreneurs in the United States to start new firms manufacturing solar panels. By 2009, though, large imports of solar panels produced by Chinese firms were driving down the market price. As panel (a) in the following figure shows, the price of solar panels, measured as dollars per watt of power produced, declined by three-quarters, from \$2.00 per watt in 2009 to \$0.36 per watt in 2014.

Panel (b) shows the situation a typical U.S. firm producing solar panels faced. The price of \$0.36 was below these firms' average total cost of producing solar panels, so the firms began to suffer losses. U.S. firms argued that Chinese firms were able to sell at low prices because they were receiving subsidies from the Chinese government, which are not allowed under international trade agreements. By 2014, the tariff the U.S. government imposed on imports of solar panels from China was as high as 78 percent. Most environmentalists opposed the tariff, arguing that if it resulted in higher prices for solar panels, fewer people would convert their homes to use solar power to generate electricity. Some U.S. firms also opposed the tariff because they use solar panels in products they export, which meant the tariff would raise their production costs.

The tariff, though, did not seem to be having much effect on the U.S. market in part because Chinese imports were being replaced by imports from Malaysia.

Why didn't the U.S. firms producing solar panels just raise the price they charged to the level they needed to break even? We have already seen that any firm that tries to raise the price of its product above the market price loses customers to competing firms. What will happen to the U.S. solar panel industry in the long run is unclear. In 2015, some U.S. firms were optimistic about the effects of an announcement from Tesla Motors that the company would be introducing home batteries. The home batteries would allow someone who had installed solar panels to store energy produced on sunny days for use on cloudy days or at night. By reducing reliance on buying electricity, the batteries had the potential to increase the demand for solar panels, raising the price enough for U.S. firms to at least break even. That development was coming too late, though, for a number of U.S. solar panel firms that had already gone out of business. The entrepreneurs who had started those businesses lost most of their investments.

12.4 Deciding Whether to Produce or to Shut Down in the Short Run

LEARNING OBJECTIVE: Explain why firms may shut down temporarily.

In panel (b) of Figure 12.5, we assumed that the firm would continue to produce even though it was operating at a loss. In the short run, a firm experiencing a loss has two choices:

1. Continue to produce
2. Stop production by shutting down temporarily

In many cases, a firm experiencing a loss will consider stopping production temporarily. Even during a temporary shutdown, however, a firm must still pay its fixed costs. For example, if the firm has signed a lease for its building, the landlord will expect to receive a monthly rent payment, even if the firm is not producing anything that month. Therefore, if a firm does not produce, it will suffer a loss equal to its fixed cost. This loss is the maximum the firm will accept. The firm will shut down if producing would cause it to lose an amount greater than its fixed cost.

A firm can reduce its loss below the amount of its total fixed cost by continuing to produce, provided that the total revenue it receives is greater than its variable cost. A firm can use the revenue over and above variable cost to cover part of its fixed cost. In this case, a firm will have a smaller loss by continuing to produce than if it shuts down.

In analyzing a firm's decision to shut down, we are assuming that its fixed costs are *sunk costs*. Remember that a **sunk cost** is a cost that has already been paid and cannot be recovered. We assume, as is usually the case, that the firm cannot recover its fixed costs by shutting down. For example, if a farmer has taken out a loan to buy land, the farmer is legally required to make the monthly loan payment whether he grows any wheat that season or not. The farmer has to spend those funds and cannot get them back, *so the farmer should treat his sunk costs as irrelevant to his short-run decision making*. For any firm, whether total revenue is greater or less than *variable cost* is the key to deciding whether to shut down or to continue producing in the short run. As long as a firm's total revenue is greater than its variable cost, it should continue to produce no matter how large or small its fixed cost is.

One option not available to a firm with losses in a perfectly competitive market is to raise its price. If the firm did raise its price, it would lose all its customers, and its sales

Sunk cost A cost that has already been paid and cannot be recovered.

would drop to zero. For example, during the past 20 years, the price of wheat has usually been high enough for a typical wheat farmer in the United States to at least break even. But in 2015, the price of wheat fell to about \$5 per bushel from more than \$7.50 per bushel three years earlier. Some wheat farmers found the \$5 per bushel price was below their break-even point. But any wheat farmer who tried to raise his price to \$7.50 per bushel would have seen his sales quickly disappear because buyers could purchase all the wheat they wanted at \$5 per bushel from the thousands of other wheat farmers.

The Supply Curve of a Firm in the Short Run

Remember that the supply curve for a firm tells us how many units of a product the firm is willing to sell at any given price. Notice that the marginal cost curve for a firm in a perfectly competitive market tells us the same thing. The firm will produce at the level of output where $MR = MC$. Because price equals marginal revenue for a firm in a perfectly competitive market, the firm will produce where $P = MC$. For any given price, we can determine from the marginal cost curve the quantity of output the firm will supply. *Therefore, a perfectly competitive firm's marginal cost curve is also its supply curve.* There is, however, an important qualification to this fact. We have seen that if a firm is experiencing a loss, it will shut down if its total revenue is less than its variable cost:

$$\text{Total revenue} < \text{Variable cost,}$$

or, in symbols:

$$(P \times Q) < VC.$$

If we divide both sides by Q , we have the result that the firm will shut down if:

$$P < AVC.$$

If the price drops below average variable cost, the firm will have a smaller loss if it shuts down and produces no output. *So, the firm's marginal cost curve is its supply curve only for prices at or above average variable cost.*

Recall that the marginal cost curve intersects the average variable cost where the average variable cost curve is at its minimum point. Therefore, as shown in Figure 12.6, the firm's supply curve is its marginal cost curve above the minimum point of the average variable cost curve. For prices below minimum average

Figure 12.6

The Firm's Short-Run Supply Curve

Because price equals marginal revenue for a firm in a perfectly competitive market, the firm will produce where $P = MC$. For any given price, we can determine the quantity of output the firm will supply from the marginal cost curve, so the marginal cost curve is the firm's supply curve. But the firm will shut down if the price falls below average variable cost. The marginal cost curve crosses the average variable cost at the firm's shutdown point at the output level Q_{SD} . For prices below P_{MIN} , the supply curve is a vertical line along the price axis, which shows that the firm will supply zero output at those prices. The red line is the firm's short-run supply curve.

The minimum point on the average variable cost curve is called the **shutdown point**, and it occurs at the output level Q_{SD} . When to Shut Down an Oil Well

In 2015, as oil prices declined, an industry analyst commented that many wells pumping shale oil had variable production costs of only \$20 per barrel. He argued that as a result, the wells would not stop producing “just because oil prices have fallen to \$45 a barrel.” Briefly explain why the

analyst thought the variable cost of producing oil from these wells, rather than the total cost, was the key to determining whether the wells would stop operating. Illustrate your answer with a graph.

Solving the Problem

Step 1: Review the chapter material. This problem is about firms deciding whether to produce when price is below average total cost, so you may want to review the section “Deciding Whether to Produce or to Shut Down in the Short Run,” which begins on page 478.

Step 2: Answer the problem by discussing the roles of variable costs and total costs in the decision of firms to continue producing in the short run.

When a firm is deciding whether to produce in the short run, the difference between variable cost and total cost is important if price has fallen below average total cost. Because the analyst makes the distinction between variable cost and total cost, we know that the owners of these wells must be suffering a loss when the price of oil is \$45 per barrel. In other words, this price must be below their average total cost. However, because the price is above average variable cost, the analyst concluded that the firms would continue to operate the wells.

Step 3: Finish answering the problem by drawing a graph to illustrate your answer from step 2. Your graph should look like this one. Note that the price is shown as being above average variable cost but below average total cost.

Figure 12.7 Firm Supply and Market Supply

We can derive the market supply curve by adding up the quantity that each firm in the market is willing to supply at each price. In panel (a), one wheat farmer is willing to supply 15,000 bushels of wheat at a price of \$7 per bushel. If every wheat farmer supplies the same amount of wheat at this price and if there are 150,000 wheat farmers, the total amount of wheat

supplied at a price of \$7 will equal 15,000 bushels per farmer \times 150,000 farmers = 2.25 billion bushels of wheat. This amount is one point on the market supply curve for wheat shown in panel (b). We can find the other points on the market supply curve by determining how much wheat each farmer is willing to supply at each price.

The Market Supply Curve in a Perfectly Competitive Industry

The market demand curve is determined by adding up the quantity demanded by each consumer in the market at each price (see Chapter 10). Similarly, the market supply curve is determined by adding up the quantity supplied by each firm in the market at each price. Each firm's marginal cost curve tells us how much that firm will supply at each price. So, the market supply curve can be derived directly from the marginal cost curves of the firms in the market. Panel (a) of Figure 12.7 shows the marginal cost curve for one wheat farmer. At a price of \$7, this wheat farmer supplies 15,000 bushels of wheat. If every wheat farmer supplies the same amount of wheat at this price and if there are 150,000 wheat farmers, the total amount of wheat supplied at a price of \$7 will be:

$$15,000 \text{ bushels per farmer} \times 150,000 \text{ farms} = 2.25 \text{ billion bushels of wheat.}$$

Panel (b) shows a price of \$7 and a quantity of 2.25 billion bushels as a point on the market supply curve for wheat. In reality, of course, not all wheat farms are alike. Some wheat farms supply more at the market price than the typical farm; other wheat farms supply less. The key point is that we can derive the market supply curve by adding up the quantity that each firm in the market is willing and able to supply at each price. [MyEconLab Concept Check](#)

12.5 "If Everyone Can Do It, You Can't Make Money at It": The Entry and Exit of Firms in the Long Run

LEARNING OBJECTIVE: Explain how entry and exit ensure that perfectly competitive firms earn zero economic profit in the long run.

In the long run, unless a firm can cover all its costs, it will shut down and exit the industry. In a market system, firms continually enter and exit industries. In this section, we will see how profits and losses provide signals to firms that lead to entry and exit.

Economic Profit and the Entry or Exit Decision

To begin, let's look more closely at how economists characterize the profits earned by the owners of a firm. Suppose Sacha Gillette decides to start her own business. After considering her skills and interests and preparing a business plan, she decides to start a cage-free egg farm rather than a restaurant or clothing boutique. After 10 years of effort, Sacha has saved \$100,000, and she is able to borrow another \$900,000 from a bank. With these funds, she buys the land, equipment, and chickens necessary to start her farm. She intends to sell the eggs in a local farmers' market. When someone invests her own funds in her firm, the opportunity cost to the firm is the return the funds would have earned in their best alternative use (see Chapter 11). If Farmer Gillette could have earned a 10 percent return on her \$100,000 in savings in their best alternative use—which might have been, for example, to buy a small restaurant—then her egg business incurs a \$10,000 opportunity cost. We can also think of this \$10,000 as being the minimum amount that Farmer Gillette needs to earn on her \$100,000 investment in her farm to remain in the industry in the long run.

Table 12.4 lists Farmer Gillette's costs. In addition to her explicit costs, we assume that she has two implicit costs: the \$10,000 that represents the opportunity cost of the funds she invested in her farm and the \$30,000 salary she could have earned managing someone else's farm instead of her own. Her total costs are \$125,000. If the market price of cage-free eggs is \$3 per dozen and Farmer Gillette sells 50,000 dozen, her total revenue will be \$150,000, and her economic profit will be \$25,000 (total revenue of \$150,000 minus total costs of \$125,000). Recall that **economic profit** equals a firm's revenues minus all its costs, implicit and explicit.

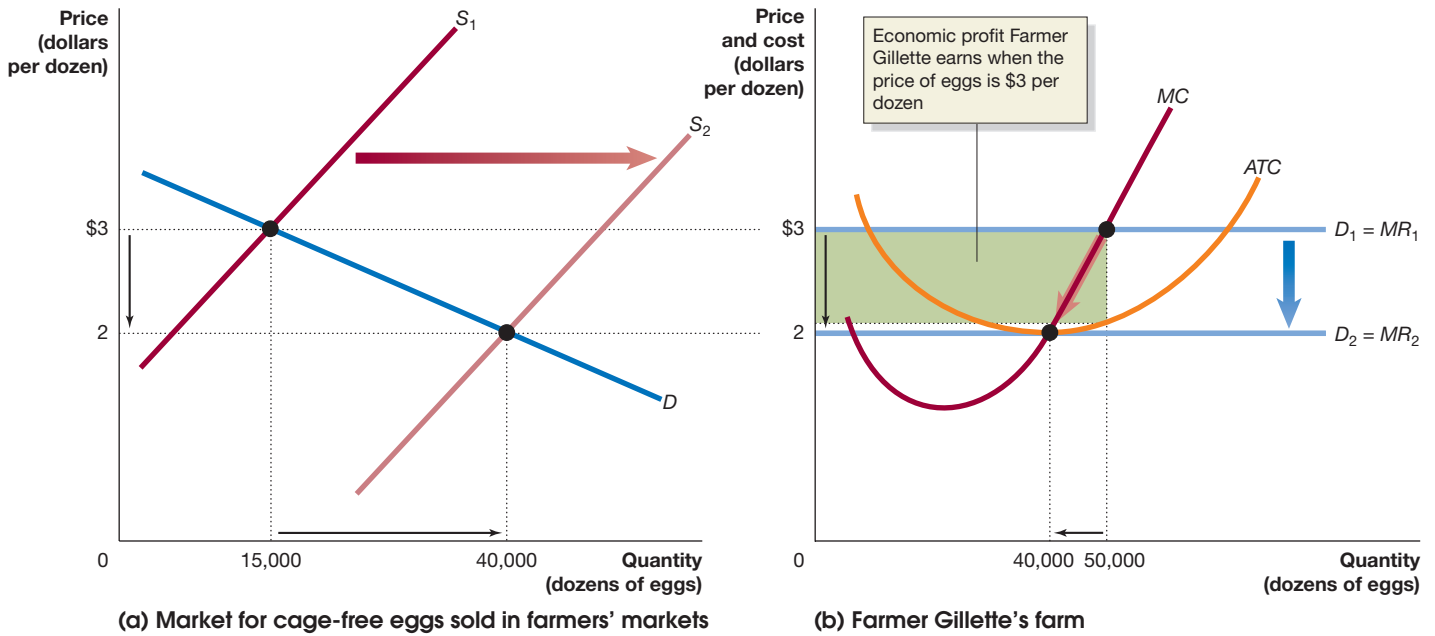

Economic profit A firm's revenues minus all its costs, implicit and explicit.

Economic Profit Leads to Entry of New Firms Unfortunately, Farmer Gillette is unlikely to earn an economic profit for very long. Suppose other farmers are just breaking even by selling regular eggs. In that case, they will have an incentive to switch to selling cage-free eggs so they can begin earning an economic profit. As we saw in the chapter opener, in recent years more farmers have been switching from producing eggs using older methods to using cage-free methods, in the hope of earning a higher profit. Remember that the more firms there are in an industry, the farther to the right the market supply curve is. Panel (a) of Figure 12.8 shows that as more farmers begin selling cage-free eggs, the market supply curve shifts to the right. Farmers will continue entering the market until the market supply curve has shifted from S_1 to S_2 .

With the supply curve at S_2 , the market price will fall to \$2 per dozen. Panel (b) shows the effect on Farmer Gillette, whom we assume has the same costs as other egg farmers. As the market price falls from \$3 to \$2 per dozen, Farmer Gillette's demand curve shifts down, from D_1 to D_2 . In the new equilibrium, Farmer Gillette is selling 40,000 dozen eggs, at a price of \$2 per dozen. She and the other egg farmers are no

Figure 12.8 The Effect of Entry on Economic Profit

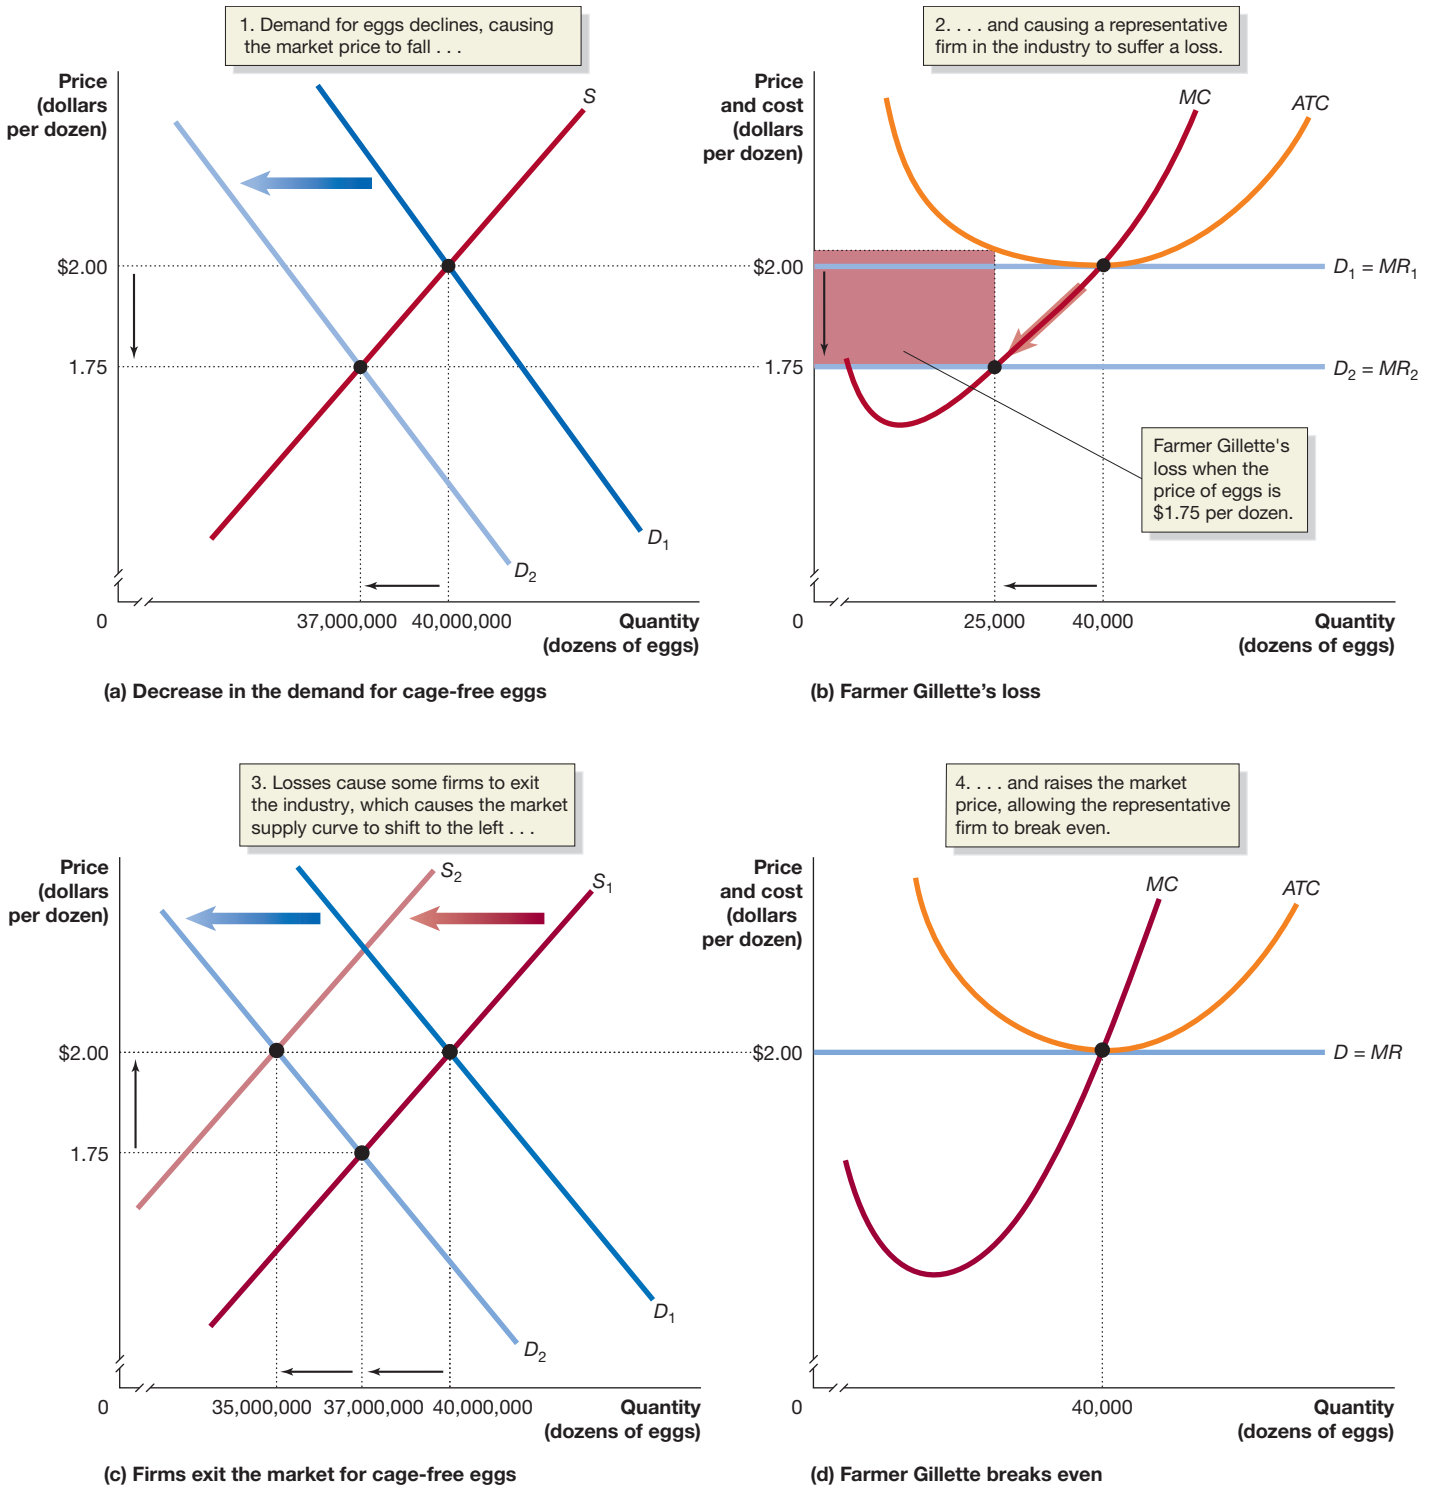

Initially, Farmer Gillette and other farmers selling cage-free eggs are able to charge \$3 per dozen and earn an economic profit. Farmer Gillette's economic profit is represented by the area of the green box in panel (b). Panel (a) shows that as other farmers begin to sell cage-free eggs, the market supply curve shifts to the right, from S_1 to S_2 , and the market price drops to \$2 per dozen. Panel (b) shows that the falling price causes

Farmer Gillette's demand curve to shift down from D_1 to D_2 , and she reduces her output from 50,000 dozen eggs to 40,000. At the new market price of \$2 per dozen, cage-free egg farmers are just breaking even: Their total revenue is equal to their total cost, and their economic profit is zero. Notice the difference in scale between the graphs in panels (a) and (b).

longer earning any economic profit. They are just breaking even, and the return on their investment is just covering the opportunity cost of these funds. New farmers will stop entering the market because the rate of return from selling cage-free eggs is now no better than they can earn by selling regular eggs.

Will Farmer Gillette continue to sell cage-free eggs even though she is just breaking even? She will because she earns as high a return on her investment as she could earn elsewhere. It may seem strange that new firms will continue to enter a market until all economic profit is eliminated and that established firms remain in a market despite not earning any economic profit. But it seems strange only because we are used to thinking in terms of accounting profit rather than *economic* profit. Remember that accounting rules generally require that only explicit costs be included on a firm's financial statements. The opportunity cost of the funds Farmer Gillette invested in her farm—\$10,000—and her forgone salary—\$30,000—are economic costs, but neither of them is an accounting cost. So, although an accountant would see Farmer Gillette as earning a profit of \$40,000, an economist would see her as just breaking even. Farmer Gillette must pay attention to her accounting profit when preparing her financial statements and when paying her income tax. But because economic profit takes into account all her costs, it gives a more accurate indication of the financial health of her farm.

Economic Losses Lead to Exit of Firms Suppose some consumers decide that they no longer want to eat eggs, whether cage-free or not. Panel (a) of Figure 12.9 shows that the demand curve for cage-free eggs will shift to the left, from D_1 to D_2 , and the market price will fall from \$2 per dozen to \$1.75. Panel (b) shows that as the price falls, a farmer like Sacha Gillette will move down her marginal cost curve to a lower level of output. At the lower level of output and lower price, she will be suffering

MyEconLab Animation

Figure 12.9 The Effect of Exit on Economic Losses

When the price of cage-free eggs is \$2 per dozen, Farmer Gillette and other farmers are breaking even. A total quantity of 40,000,000 dozen eggs is sold in the market. Farmer Gillette sells 40,000 dozen. Panel (a) shows a decline in the demand for cage-free eggs from D_1 to D_2 that reduces the market price to \$1.75 per dozen. Panel (b) shows that the falling price causes Farmer Gillette's demand curve to shift down from D_1 to D_2 and her output to fall from 40,000 to 25,000 dozen. At a market price of \$1.75 per dozen, farmers

have losses, represented by the area of the red box. As a result, some farmers will exit the market, which shifts the market supply curve to the left. Panel (c) shows that exit continues until the supply curve has shifted from S_1 to S_2 and the market price has risen from \$1.75 back to \$2.00. Panel (d) shows that with the price back at \$2.00, Farmer Gillette will break even. In the new market equilibrium in panel (c), total sales of cage-free eggs have fallen from 40,000,000 to 35,000,000 dozen.

an **economic loss** because she will not cover all her costs. As long as price is above average variable cost, she will continue to produce in the short run, even when suffering losses. But in the long run, firms will exit an industry if they are unable to cover all their costs. In this case, some farmers will switch from producing eggs to producing other agricultural products or will leave farming.

Panel (c) of Figure 12.9 shows that as firms exit from selling cage-free eggs, the market supply curve shifts to the left. Firms will continue to exit, and the supply curve will continue to shift to the left until the price has risen back to \$2 and the market supply curve is at S_2 . Panel (d) shows that when the price is back to \$2, the remaining firms in the industry will be breaking even.

MyEconLab Concept Check

Economic loss The situation in which a firm's total revenue is less than its total cost, including all implicit costs.

Long-Run Equilibrium in a Perfectly Competitive Market

We have seen that economic profits attract firms to enter an industry. The entry of firms forces down the market price until a typical firm is breaking even. Economic losses cause firms to exit an industry. The exit of firms forces up the equilibrium market price until the typical firm is breaking even. In **long-run competitive equilibrium**, entry and exit have resulted in the typical firm breaking even. In the long run, firms can also vary their scale by becoming larger or smaller (see Chapter 11). The *long-run average cost curve* shows the lowest cost at which a firm is able to produce a given quantity of output in the long run. So, we would expect that in the long run, competition drives the market price to the minimum point on the typical firm's long-run average cost curve.

The long run in selling cage-free eggs appears to be several years, which is the amount of time it takes farmers to convert from using traditional methods of producing eggs to cage-free methods. As we discussed in the chapter opener, the number of farmers producing cage-free eggs has been rapidly increasing, but cage-free eggs are still more profitable than eggs produced using conventional methods. So we can predict that in the coming years more farmers will begin producing eggs using cage-free methods.

Firms in perfectly competitive markets are in a constant struggle to stay one step ahead of their competitors. They are always looking for new ways to provide a product, such as selling cage-free eggs. It is possible for firms to find ways to earn an economic profit for a while, but competition typically eliminates that profit in just a few years. This observation is not restricted to agriculture. In any perfectly competitive market, an opportunity to make an economic profit never lasts long. As Sharon Oster, an economist at Yale University, has put it: "If everyone can do it, you can't make money at it."

MyEconLab Concept Check

Long-run competitive equilibrium The situation in which the entry and exit of firms has resulted in the typical firm breaking even.

The Long-Run Supply Curve in a Perfectly Competitive Market

If a typical poultry farmer selling cage-free eggs breaks even at a price of \$2 per dozen, in the long run, the market price will always return to this level. If an increase in demand causes the market price to rise above \$2, farmers will be earning an economic profit. That profit will attract additional farmers into the market, and the market supply curve will shift to the right until the price is back to \$2. Panel (a) in Figure 12.10 illustrates the long-run effect of an increase in demand. An increase in demand from D_1 to D_2 causes the market price to rise temporarily from \$2 per dozen to \$3. At this price, farmers are making an economic profit selling cage-free eggs, but the profit attracts the entry of new farmers. The result is an increase in supply from S_1 to S_2 , which forces the price back down to \$2 per dozen and eliminates the economic profit.

Similarly, if a decrease in demand causes the market price to fall below \$2, farmers will experience an economic loss. The loss will cause some farmers to exit the market, the supply curve will shift to the left, and the price will return to \$2. Panel (b)

MyEconLab Animation

Figure 12.10 The Long-Run Supply Curve in a Perfectly Competitive Industry

Panel (a) shows that an increase in demand for cage-free eggs will lead to a temporary increase in price from \$2.00 to \$3.00 per dozen, as the market demand curve shifts to the right, from D_1 to D_2 . The entry of new firms shifts the market supply curve to the right, from S_1 to S_2 , which will cause the price to fall back to its long-run level of \$2.00. Panel (b) shows that a decrease in demand will lead to a temporary decrease in price from \$2.00 to \$1.75 per dozen, as the market demand

curve shifts to the left, from D_1 to D_2 . The exit of firms shifts the market supply curve to the left, from S_1 to S_2 , which causes the price to rise back to its long-run level of \$2.00. The long-run supply curve (S_{LR}) shows the relationship between market price and the quantity supplied in the long run. In this case, the long-run supply curve is a horizontal line.

in Figure 12.10 illustrates the long-run effect of a decrease in demand. A decrease in demand from D_1 to D_2 causes the market price to fall temporarily from \$2 per dozen to \$1.75. At this price, farmers are suffering an economic loss, but the loss causes some farmers to exit the market for selling cage-free eggs. The result is a decrease in supply from S_1 to S_2 , which forces the price back up to \$2 per dozen and eliminates the loss.

The **long-run supply curve** shows the relationship in the long run between market price and the quantity supplied. In the long run, the price will be \$2 per dozen, no matter how many eggs are produced. So, as Figure 12.10 shows, the long-run supply curve (S_{LR}) is a horizontal line at a price of \$2. Remember that the price returns to \$2 in the long run because at this price a typical firm in the industry just breaks even. The typical firm breaks even because \$2 is at the minimum point on the firm's average total cost curve. We can draw the important conclusion that *in the long run, a perfectly competitive market will supply whatever amount of a good consumers demand at a price determined by the minimum point on the typical firm's average total cost curve.*

Because the position of the long-run supply curve is determined by the minimum point on the typical firm's average total cost curve, anything that raises or lowers the costs of the typical firm in the long run will cause the long-run supply curve to shift. For example, if the cost of the feed for chickens increases and the cost of the feed adds \$0.25 per dozen to every farmer's cost of producing cage-free eggs, the long-run supply curve will shift up by \$0.25.

In the Apple Apps Store, Easy Entry Makes the Long Run Pretty Short

One reason for the popularity of Apple's iPhones and iPads is the section of Apple's iTunes music and video store devoted to applications (or "apps"). Independent software programmers write apps that Apple makes available in the store in exchange for receiving 30 percent of the revenue the app generates. Major software companies, as well as individuals writing their first software programs, have posted games, calendars, dictionaries, and many other types of apps to the App Store.

At first, app developers were able to earn significant amounts by charging for downloads. For example, Hogrocket, a three-person company, developed the game *Tiny Invaders* and began selling it in the App Store in 2011. Initially, the company was successful in selling the app for \$2.99. As we have seen, though, when firms earn an economic profit in a market, other firms have a strong economic incentive to enter that market. By 2015, about 750 new games were being added to the App Store *per day*. This flood of games forced Hogrocket to lower the price of its game to \$0.99. At that price, though, the company was unable to sell enough downloads to break even, and the firm had to shut down.

The competition in the App Store is so intense that by 2015, many people were unwilling to download games unless they were free. According to one estimate, fewer than one-third of smartphone and tablet users will purchase an app during the year. Some app designers have tried the strategy of allowing apps to be downloaded for free while attempting to earn revenue by forcing users to see advertisements before the app opens or while it runs. Many people find these advertisements annoying, though, so developers have begun offering free apps that lack advertisements but where the developers earn revenue from users making in-app purchases. For instance, in the popular game *Candy Crush Saga*, users are given free turns. After they have used them up, they can wait 30 minutes for another free turn or they can pay a small amount to immediately receive five more turns. Similarly, in the *Clash of Clans* game, players can slowly build up their villages' defenses and their armies for free or they can make an in-app purchase of "gems" to speed up the process.

Still, only about 3 percent of people who play these games make any in-app purchases. That leaves developers dependent on "whales" who make \$50 to \$100 per month in in-app game purchases. Only the best games can attract whale players and survive the intense competition of the App Store. And even these games have to constantly add new features if they hope to keep users from switching to playing newly released games. Yet, the incentive to develop new games remains substantial, with U.S. players of app games spending nearly \$2 billion per year on them.

In a competitive market, earning an economic profit in the long run is extremely difficult. And the ease of entering the market for smartphone and tablet apps has made the long run pretty short.

Increasing-Cost and Decreasing-Cost Industries

Any industry in which the typical firm's average costs do not change as the industry expands production will have a horizontal long-run supply curve, like the one in Figure 12.10. These industries, including the egg industry, are called *constant-cost industries*. It's possible, however, for the typical firm's average costs to change as an industry expands.

For example, if an input used in producing a good is available in only limited quantities, the cost of the input will rise as the industry expands. If only a limited amount of land is available on which to grow the grapes to make a certain variety of wine, an increase in demand for wine made from these grapes will result in competition for the land and will drive up its price. As a result, more of the wine will be produced in the long run only if the price rises to cover the typical firm's higher average cost. In this case, the long-run supply curve will slope upward. Industries with upward-sloping long-run supply curves are called *increasing-cost industries*.

Finally, in some cases, the typical firm's costs may fall as the industry expands. Suppose that someone invents a new smartwatch that uses as an input a specialized memory chip that is currently produced only in small quantities. If demand for the smartwatch increases, firms that produce smartwatches will increase their orders for the memory chip. If there are *economies of scale* in producing a good, the average cost of producing it will decline as output increases (see Chapter 11). If there are economies of scale in producing this memory chip, the average cost of producing it will fall, and competition will result in its price falling as well. This price decline, in turn, will lower the average cost of producing the new smartwatch. In the long run, competition will force the price of the smartwatch to fall to the level of the typical firm's new lower average cost. In this case, the long-run supply curve will slope downward. Industries with downward-sloping long-run supply curves are called *decreasing-cost industries*.

12.6 Perfect Competition and Efficiency

LEARNING OBJECTIVE: Explain how perfect competition leads to economic efficiency.

Notice how powerful consumers are in a market system. If consumers want more cage-free eggs, the market will supply them. More cage-free eggs are supplied not because a government bureaucrat in Washington, DC, or an official in a farmers' association gives orders. The additional eggs are produced because an increase in demand results in higher prices and a larger profit from selling cage-free eggs. Farmers, trying to get the highest possible return on their investments, begin to switch from producing eggs the old way to producing eggs using cage-free methods. If consumers lose their taste for these eggs and demand falls, the process works in reverse.

Productive Efficiency

In a market system, consumers get as many cage-free eggs as they want, produced at the lowest average cost possible. The forces of competition will drive the market price to the typical firm's minimum average cost. **Productive efficiency** refers to the situation in which a good or service is produced at the lowest possible cost. As we have seen, perfect competition results in productive efficiency.

The managers of every firm strive to earn an economic profit by reducing costs. But in a perfectly competitive market, other firms quickly copy ways of reducing costs. Therefore, in the long run, only the consumer benefits from cost reductions.

Productive efficiency The situation in which a good or service is produced at the lowest possible cost.

Solved Problem 12.6

How Productive Efficiency Benefits Consumers

Financial writer Michael Lewis once remarked, "The sad truth, for investors, seems to be that most of the benefits of new technologies are passed right through to consumers free of charge."

- What do you think Lewis means by the benefits of new technology being "passed right through to consumers free of charge"? Use a graph like Figure 12.8 on page 483 to illustrate your answer.
- Explain why this result is a "sad truth" for investors.

Solving the Problem

Step 1: Review the chapter material. This problem is about perfect competition and efficiency, so you may want to review the section “Perfect Competition and Efficiency,” which begins on page 488.

Step 2: Use the concepts from this chapter to explain what Lewis means. By “new technologies,” Lewis means new products—such as smartwatches or 4K television sets—or lower-cost ways of producing existing products. In either case, new technologies will allow firms to earn an economic profit for a while, but the profit will lead new firms to enter the market in the long run.

Step 3: Use a graph like Figure 12.8 on page 483 to illustrate why the benefits of new technologies are “passed right through to consumers free of charge.” Figure 12.8 shows the situation in which a firm is making an economic profit in the short run but the profit is eliminated by entry in the long run. We can draw a similar graph to analyze what happens in the long run in the market for 4K televisions.

(a) Market for 4K televisions

(b) One firm selling 4K televisions

When 4K televisions were first introduced, prices were high, and only a few firms were in the market. Panel (a) shows that the initial equilibrium price in the market for 4K televisions is P_1 . Panel (b) shows that at this price, the typical firm in the industry is earning an economic profit, which is shown by the green-shaded box. The economic profit attracts new firms into the industry. This entry shifts the market supply curve from S_1 to S_2 in panel (a) and lowers the equilibrium price from P_1 to P_2 . Panel (b) shows that at the new market price, P_2 , the typical firm is breaking even. Therefore, 4K televisions are being produced at the lowest possible cost, and productive efficiency is achieved. Consumers receive the new technology “free of charge” in the sense that they only have to pay a price equal to the lowest possible cost of production.

Step 4: Answer part (b) by explaining why the result in part (a) is a “sad truth” for investors. We have seen in answering part (a) that in the long run, firms only break even on their investment in producing high-technology goods. That result implies that investors in these firms are also unlikely to earn an economic profit in the long run.

Extra Credit: Lewis is using a key result from this chapter: In the long run, the entry of new firms competes away economic profit. Notice that, strictly speaking, the high-technology industries Lewis is discussing are not perfectly competitive. Smart-watches and 4K televisions, for instance, are not identical, and each smartphone company produces a quantity large enough to affect the market price. However, as we will see in the next chapter, these deviations from perfect competition do not change the important conclusion that the entry of new firms benefits consumers by forcing prices down to the level of average cost. In fact, the price of 4K televisions dropped by more than 50 percent within three years of their first becoming widely available.

Your Turn: For more practice, do related problems 6.6, 6.7, and 6.8 on page 498 at the end of this chapter.

Allocative Efficiency

Not only do perfectly competitive firms produce goods and services at the lowest possible cost, they also produce the goods and services that consumers value most. Firms will produce a good up to the point where the marginal cost of producing another unit is equal to the marginal benefit consumers receive from consuming that unit. In other words, firms will supply all those goods that provide consumers with a marginal benefit at least as great as the marginal cost of producing them. This result holds because:

1. The price of a good represents the marginal benefit consumers receive from consuming the last unit of the good sold.
2. Perfectly competitive firms produce up to the point where the price of the good equals the marginal cost of producing the last unit.
3. Therefore, firms produce up to the point where the last unit provides a marginal benefit to consumers equal to the marginal cost of producing it.

In other words, entrepreneurs in a competitive market system efficiently *allocate* labor, machinery, and other inputs to produce the goods and services that best satisfy consumer wants. In this way, perfect competition achieves **allocative efficiency**. As we will explore in the next few chapters, many goods and services sold in the U.S. economy are not produced in perfectly competitive markets. Nevertheless, productive efficiency and allocative efficiency are useful benchmarks against which to compare the actual performance of the economy.

MyEconLab Concept Check

Allocative efficiency A state of the economy in which production represents consumer preferences; in particular, every good or service is produced up to the point where the last unit provides a marginal benefit to consumers equal to the marginal cost of producing it.

Economics in Your Life

Are You an Entrepreneur?

At the beginning of the chapter, we asked you to think about why you can charge only a relatively low price for babysitting or mowing lawns. In the chapter, we saw that firms selling products in competitive markets can't charge prices higher than those being charged by competing firms. The market for babysitting and mowing lawns is very competitive because in most neighborhoods, there are many teenagers willing to supply these services. The price you can charge for babysitting may not be worth your time when you are 20 but is enough to cover the opportunity cost of a 14-year-old eager to enter the market. In other words, the ease of entry into babysitting and mowing lawns is high. So, in your career as a teenage entrepreneur, you may have become familiar with one of the lessons of this chapter: A firm in a competitive market has no control over price.

Conclusion

The competitive forces of the market impose relentless pressure on firms to produce new and better goods and services at the lowest possible cost. Firms that fail to adequately anticipate changes in consumer tastes or that fail to adopt the latest and most efficient technology do not survive in the long run. In the nineteenth century, the biologist Charles Darwin developed a theory of evolution based on the idea of the “survival of the fittest.” Only those plants and animals that are best able to adapt to the demands of their environment are able to survive. Darwin first realized the important role that the struggle for existence plays in the natural world after reading early nineteenth-century economists’ descriptions of the role it plays in the economic world. Just as “survival of the fittest” is the rule in nature, so it is in the economy.

At the start of this chapter, we saw that there are four market structures: perfect competition, monopolistic competition, oligopoly, and monopoly. Now that we have studied perfect competition, in the following chapters we move on to the other three market structures.

Perfectly Competitive Markets, pages 467–469

LEARNING OBJECTIVE: Explain what a perfectly competitive market is and why a perfect competitor faces a horizontal demand curve.

Summary

A **perfectly competitive market** must have many buyers and sellers, firms must be producing identical products, and there must be no barriers to new firms entering the market. The demand curve for a good or service produced in a perfectly competitive market is downward sloping, but the demand curve for the output of one firm in a perfectly competitive market is a horizontal line at the market price. Firms in perfectly competitive markets are **price takers**, and their sales drop to zero if they attempt to charge more than the market price.

Review Questions

- 1.1 What are the three conditions for a market to be perfectly competitive?
- 1.2 What is a price taker? When are firms likely to be price takers?
- 1.3 Briefly explain why a firm in a perfectly competitive market would generally face a horizontal demand curve. What implications do you think this has for the price of its product?

Problems and Applications

- 1.4 Explain whether each of the following is a perfectly competitive market or not. For each market that is not perfectly competitive, explain why it is not.
 - a. Books
 - b. Pizza market
 - c. IT companies
 - d. Luxury goods
- 1.5 The late Nobel Prize–winning economist George Stigler once wrote, “the most common and most important criticism of perfect competition ... [is] that it is unrealistic.” Since few firms sell identical products in markets where there are no barriers to entry, why do economists believe that the model of perfect competition is important?

1.6 (Related to the **Don't Let This Happen to You** on page 468)

Explain whether you agree with the following remark:

In a perfectly competitive market each firm faces a horizontal demand curve. This means that the firm will be unable to sell its product at a price higher than the market price, because it will lose all its customers. Then, the firm will find it profitable to lower its price, so to attract more customers and sell more, therefore increasing its profits.

- 1.7 The financial writer Andrew Tobias described an incident that occurred when he was a student at the Harvard Business School: Each student in the class was given large amounts of information about a particular firm and asked to determine a pricing strategy for the firm. Most of the students spent hours preparing their answers and came to class carrying many sheets of paper with their calculations. Tobias came up with the correct answer after just a few minutes and without having made any calculations. When his professor called on him in class for an answer, Tobias stated: “The case said the XYZ Company was in a very competitive industry ... and the case said that the company had all the business it could handle.” Given this information, what price do you think Tobias argued the company should charge? Briefly explain. (Tobias says the class greeted his answer with “thunderous applause.”)

- 1.8 In 2015, some beer drinkers filed a lawsuit against Anheuser-Busch, the brewer of Beck's beer. The beer drinkers claimed that Beck's was marketed as an authentic German beer but was actually brewed in St. Louis. Other breweries have established facilities in Canada so they can truthfully claim that their beers are “imported.” If the market for beer were perfectly competitive, would the location of breweries matter to consumers? Briefly explain.

12.2

How a Firm Maximizes Profit in a Perfectly Competitive Market, pages 469–472

LEARNING OBJECTIVE: Explain how a firm maximizes profit in a perfectly competitive market.

Summary

Profit is the difference between total revenue (TR) and total cost (TC). **Average revenue (AR)** is total revenue divided by the quantity of the product sold. A firm maximizes profit by producing the level of output where the difference between revenue and cost is the greatest. This is the same level of output where marginal revenue is equal to marginal cost. **Marginal revenue (MR)** is the change in total revenue from selling one more unit.

Review Questions

- 2.1 Explain the relationships between the price of a product in a perfectly competitive market, the average revenue of a firm in that market, and its marginal revenue.
- 2.2 Explain why at the level of output where the difference between TR and TC is at its maximum positive value, MR must equal MC .
- 2.3 Explain why it is true that for a firm in a perfectly competitive market, the profit-maximizing condition $MR = MC$ is equivalent to the condition $P = MC$.

Problems and Applications

- 2.4 A student argues: “To maximize profit, a firm should produce the quantity where the difference between marginal

revenue and marginal cost is the greatest. If a firm produces more than this quantity, then the profit made on each additional unit will be falling.” Briefly explain whether you agree with this reasoning.

- 2.5 Why don’t firms maximize revenue rather than profit? Briefly explain whether a firm that maximized revenue would be likely to produce a smaller or larger quantity than if it were maximizing profit.
- 2.6 Refer to Table 12.3 on page 471. Suppose the price of wheat falls to \$5.50 per bushel. How many bushels of wheat will Farmer Parker produce, and how much profit will he make? Briefly explain.
- 2.7 Refer to Table 12.3 on page 471. Suppose that the marginal cost of wheat is \$0.50 higher for every bushel of wheat produced. For example, the marginal cost of producing the eighth bushel of wheat is now \$9.50. Assume that the price of wheat remains \$7 per bushel. Will this increase in marginal cost change the profit-maximizing level of production for Farmer Parker? Briefly explain. How much profit will Farmer Parker make now?
- 2.8 In Table 12.3 on page 471, what are Farmer Parker’s fixed costs? Suppose that his fixed costs increase by \$10. Will this increase change the profit-maximizing level of production for Farmer Parker? Briefly explain. How much profit will Farmer Parker make now?

12.3

Illustrating Profit or Loss on the Cost Curve Graph, pages 472–478

LEARNING OBJECTIVE: Use graphs to show a firm’s profit or loss.

Summary

From the definitions of profit and average total cost, we can develop the following expression for the relationship between total profit and average total cost: $\text{Profit} = (P - ATC) \times Q$. Using this expression, we can determine the area showing profit or loss on a cost curve graph: The area of profit or loss is a rectangle with a height equal to price minus average total cost (for profit) or average total cost minus price (for loss) and a base equal to the quantity of output.

Review Questions

- 3.1 Draw a graph showing a firm that is making a profit in a perfectly competitive market. Be sure your graph includes the firm’s demand curve, marginal revenue curve, marginal cost curve, average total cost curve, and average variable cost curve and make sure to indicate the area representing the firm’s profit.
- 3.2 Draw a graph showing a firm that is operating at a loss in a perfectly competitive market. Be sure your graph

includes the firm’s demand curve, marginal revenue curve, marginal cost curve, average total cost curve, and average variable cost curve and make sure to indicate the area representing the firm’s loss.

Problems and Applications

- 3.3 (Related to Solved Problem 12.3 on page 474) Frances sells pencils in the perfectly competitive pencil market. Her output per day and her costs are as follows:

Output per Day	Total Cost
0	\$1.00
1	2.50
2	3.50
3	4.20
4	4.50
5	5.20
6	6.80
7	8.70
8	10.70
9	13.00

- a. If the current equilibrium price in the pencil market is \$1.80, how many pencils will Frances produce, what price will she charge, and how much profit (or loss) will she make? Draw a graph to illustrate your answer. Your graph should be clearly labeled and should include Frances's demand, ATC, AVC, MC, and MR curves; the price she is charging; the quantity she is producing; and the area representing her profit (or loss).
- b. Suppose the equilibrium price of pencils falls to \$1.00 per pair. Now how many pencils will Frances produce, what price will she charge, and how much profit (or loss) will she make? Show your work. Draw a graph to illustrate this situation, using the instructions in part (a).
- c. Suppose the equilibrium price of pencils falls to \$0.25. Now how many pencils will Frances produce, what price will she charge, and how much profit (or loss) will she make?

3.4 (Related to Solved Problem 12.3 on page 474) Review Solved Problem 12.3 and then answer the following: Suppose the equilibrium price of basketballs falls to \$2.50. Now how many basketballs will Andy produce? What price will he charge? How much profit (or loss) will he make?

3.5 (Related to the Don't Let This Happen to You on page 476) A student guesses the quantity at which a firm maximizes profits looking at the graph below: "I think that the firm maximizes profits by either producing A or C, because the price is equal to the marginal cost. It would also be profitable to produce B, because the marginal cost at B is equal to the average total cost. It would make zero profits by producing D, because the price is equal to the average total cost." Is the student right?

3.6 An article in the *Wall Street Journal* discussed the financial results for BlackBerry, the smartphone and

software company: "Revenue tumbled 32% from a year earlier to \$658 million in the quarter ended May 30 from \$966 million a year earlier. . . . BlackBerry posted profit of \$68 million . . . up from \$23 million a year earlier." How is it possible for BlackBerry's revenue to decrease but its profit to increase? Doesn't BlackBerry have to maximize its revenue to maximize its profit? Briefly explain.

3.7 (Related to the Making the Connection on page 477)

Suppose that the price of cut wood decreases, lowering the cost of furniture. What effect would this have on the U.S. furniture industry, in general, and on U.S. companies, in particular? Illustrate your answer using two graphs, one for the industry and one for companies. The one for industry should underline the shifts in market demand and supply curves, as well as equilibrium market price. The other should include the demand curve of the company, marginal revenue, marginal cost curve, and average total cost curve.

3.8 The following graph represents the situation of Marguerite's Caps, a firm selling caps in the perfectly competitive cap industry:

- a. How much output should Marguerite produce to maximize her profits?
- b. How much profit will she earn?
- c. Suppose Marguerite decides to shut down. What would her loss be?

12.4 Deciding Whether to Produce or to Shut Down in the Short Run, pages 478–481

LEARNING OBJECTIVE: Explain why firms may shut down temporarily.

Summary

In deciding whether to shut down or produce in the short run, a firm should ignore its *sunk costs*. A **sunk cost** is a cost that has already been paid and that cannot be recovered. In the short run, a firm continues to produce as long as its price is at least equal to its average variable cost. A perfectly competitive firm's **shutdown point** is the minimum point on the firm's average

variable cost curve. If price falls below average variable cost, the firm shuts down in the short run. For prices above the shutdown point, a perfectly competitive firm's marginal cost curve is also its supply curve.

Review Questions

- 4.1 What is the difference between a firm's shutdown point in the short run and in the long run? Why are firms willing to accept losses in the short run but not in the long run?
- 4.2 What is the relationship between a perfectly competitive firm's marginal cost curve and its supply curve?
- 4.3 How is the market supply curve derived from the supply curves of individual firms?

Problems and Applications

- 4.4 Consider a firm in each of the following three situations. For each situation, carefully explain whether the firm will produce in the short run or shut down in the short run.

	Situation 1	Situation 2	Situation 3
Price	\$10	\$10	\$10
Quantity	1,000	1,000	1,000
Variable cost	\$5,000	\$5,000	\$11,000
Fixed cost	\$5,000	\$6,000	\$5,000
Marginal cost of 1,000th unit	\$10	\$10	\$10

- 4.5 Ed Scahill produces table lamps in the perfectly competitive desk lamp market.
 - a. Fill in the missing values in the following table.

Output per Week	Total Cost	AFC	AVC	ATC	MC
0	\$100				
1	150				
2	175				
3	190				
4	210				
5	240				
6	280				
7	330				
8	390				
9	460				
10	540				

- b. Suppose the equilibrium price in the desk lamp market is \$50. How many table lamps should Ed produce, and how much profit will he make?
 - c. If next week the equilibrium price of desk lamps drops to \$30, should Ed shut down? Explain.
- 4.6 Matt Rafferty produces hiking boots in the perfectly competitive hiking boots market.
 - a. Fill in the missing values in the following table.

Output per Week	Total Cost	AFC	AVC	ATC	MC
0	\$100.00				
1	155.70				
2	205.60				
3	253.90				
4	304.80				
5	362.50				
6	431.20				
7	515.10				
8	618.40				
9	745.30				
10	900.00				

- b. Suppose the equilibrium price in the hiking boots market is \$100. How many pairs of boots should Matt produce, what price should he charge, and how much profit will he make?
 - c. If next week the equilibrium price of boots drops to \$65, how many pairs of boots should Matt produce, what price should he charge, and how much profit (or loss) will he make?
 - d. If the equilibrium price of boots falls to \$50, how many pairs of boots should Matt produce, what price should he charge, and how much profit (or loss) will he make?

- 4.7 The following graph represents the situation of a perfectly competitive firm. Indicate on the graph the areas that represent the following:

- a. Total cost
 - b. Total revenue
 - c. Variable cost
 - d. Profit or loss
- Briefly explain whether the firm will continue to produce in the short run.

4.8 According to an article in the *New York Times*, interest payments on bank loans make up more than half the costs of a typical solar panel manufacturer. The owner of a firm that imports solar panels made this observation about solar panel manufacturers: “So as long as companies can cover their variable costs and earn at least some revenue to put toward interest payments, they will continue to operate even at a loss.”

- Are the interest payments these firms make a variable cost or a fixed cost? Briefly explain.
- Does the quotation accurately describe the behavior of solar panel manufacturers in the short run? Does it accurately describe their behavior in the long run? Briefly explain.

4.9 (Related to Solved Problem 12.4 on page 480) Suppose you decide to open a copy store. You rent store space (signing a one-year lease to do so), and you take out a loan at a local bank and use the money to purchase 10 copiers. Six months later, a large chain opens a copy store two

blocks away from yours. As a result, the revenue you receive from your copy store, while sufficient to cover the wages of your employees and the costs of paper and utilities, doesn’t cover all your rent and the interest and repayment costs on the loan you took out to purchase the copiers. Briefly explain whether you should continue operating your business.

4.10 (Related to Solved Problem 12.4 on page 480) According to an article in the *Wall Street Journal*, in 2007 the insurance company AXA Equitable signed a long-term lease on 2 million square feet of office space in a skyscraper on Sixth Avenue in Manhattan in New York City. In 2013, AXA decided that it only needed 1.7 million square feet of office space, so it subleased 300,000 square feet of space to several other firms. Although AXA is paying a rent of \$88 per square foot on all 2 million square feet it is leasing, it is only receiving \$40 per square foot from the firms it is subleasing the 300,000 square feet to. Briefly explain why AXA’s actions might make economic sense in the short run. Would these actions make sense in the long run? Briefly explain.

“If Everyone Can Do It, You Can’t Make Money at It”: The Entry and Exit of Firms in the Long Run, pages 481–488

LEARNING OBJECTIVE: Explain how entry and exit ensure that perfectly competitive firms earn zero economic profit in the long run.

Summary

Economic profit is a firm’s revenue minus all its costs, implicit and explicit. **Economic loss** is the situation in which a firm’s total revenue is less than its total cost, including all implicit costs. If firms make an economic profit in the short run, new firms enter the industry until the market price has fallen enough to wipe out the profit. If firms suffer an economic loss, firms exit the industry until the market price has risen enough to wipe out the loss. **Long-run competitive equilibrium** is the situation in which the entry and exit of firms has resulted in the typical firm breaking even. The **long-run supply curve** shows the relationship between market price and the quantity supplied.

Review Questions

- When are firms likely to enter an industry? When are they likely to exit an industry?
- Explain the implications of economic profit and accounting profit on the long-run equilibrium of a perfectly competitive market.
- Discuss the shape of the long-run supply curve in a perfectly competitive market. Suppose that a perfectly competitive market is initially at long-run equilibrium and then there is a permanent decrease in the demand for the product. Draw a graph showing how the market adjusts in the long run.

Problems and Applications

- Suppose an assistant professor of economics is earning a salary of \$75,000 per year. One day she quits her job, sells \$100,000 worth of bonds that had been earning 3 percent per year, and uses the funds to open a bookstore. At the end of the year, she shows an accounting profit of \$80,000 on her income tax return. What is her economic profit?
- A study analyzed a pharmaceutical firm’s costs to develop a prescription drug and receive government approval. An article in the *Wall Street Journal* describing the study noted that included in the firm’s costs was “the return that could be gained if the money [used to develop the drug] were invested elsewhere.” Briefly explain whether you agree that this return should be included in the firm’s costs.

- (Related to the Chapter Opener on page 465)** The following questions are about long-run equilibrium in the market for cage-free eggs.
 - As described in the chapter opener, was the market for cage-free eggs in 2015 in long run equilibrium? Briefly explain.
 - What would we expect to happen to the price of cage-free eggs and the quantity of cage-free eggs produced in the long run? Briefly explain.
 - In January 2015, California began requiring that all eggs sold in the state be cage-free. Dunkin’ Donuts also announced that it would eventually use only cage-free

eggs in its breakfast sandwiches nationwide. Other firms made similar announcements. What effect will this increased demand have on the long-run price of cage-free eggs? Briefly explain.

- 5.7 In panel (b) of Figure 12.9 on page 484, Sacha Gillette reduces her output from 40,000 to 25,000 dozen eggs when the price falls to \$1.75. At this price and this output level, she is operating at a loss. Why doesn't she just continue charging the original \$2.00 and continue producing 40,000 dozen eggs?
- 5.8 According to an article in the *Wall Street Journal*, rapid growth in consumer demand for natural and organic food helped make the Whole Foods supermarket chain very profitable. But according to that same story, "its accomplishment drew broad new competition, from mainstream retailers like Kroger and Safeway Inc. and upstarts like Sprouts Farmers Market Inc. and Fresh Market Inc." As a result, the prices of the organic food sold by Whole Foods and these other stores has declined, and so have the stores' profits. Illustrate what happened to Whole Foods and to the market for organic food sold in supermarkets using two graphs: One graph should illustrate the situation for Whole Foods, and the other graph should show what happened in the market for organic foods. Be sure that all curves in your graphs are correctly labeled and that you show any shifts in the curves as a result of increased competition in the market for organic foods.

Perfect Competition and Efficiency, pages 488–490

LEARNING OBJECTIVE: Explain how perfect competition leads to economic efficiency.

Summary

Perfect competition results in **productive efficiency**, which means that goods and services are produced at the lowest possible cost. Perfect competition also results in **allocative efficiency**, which means the goods and services are produced up to the point where the last unit provides a marginal benefit to consumers equal to the marginal cost of producing it.

Consumer advocacy groups charged at a press conference yesterday that there is widespread price gouging in the sale of pencils. They released a study showing that whereas the average retail price of pencils was \$1.00, the average cost of producing pencils was only \$0.50. “Pencils can be produced without complicated machinery or highly skilled workers, so there is no justification for companies charging a price that is twice what it costs them to produce the product. Pencils are too important in the life of every American for us to tolerate this sort of price gouging any longer,” said George Grommet, chief spokesperson for the consumer groups. The consumer groups advocate passage of a law that would allow companies selling pencils to charge a price no more than 20 percent greater than their average cost of production.

Do you believe such a law would be advisable in a situation like this? Explain.

- 6.10** Although New York State is second only to Washington State in production of apples, its production has been declining during the past 20 years. City. Today, only about 6,000 acres remain. As it became difficult for apple growers in the county to compete with lower-cost producers elsewhere, the resources these entrepreneurs were using to produce apples—particularly land—became more valuable in other uses. Many farmers sold their land to housing developers. Suppose a nutritionist develops a revolutionary new diet that involves eating 10 apples per day. The new diet becomes wildly popular. Is Chipotle the New McDonald's?

Steve Ells majored in art history at the University of Colorado before attending the Culinary Institute of America and working as a chef in San Francisco. In 1993, he opened Chipotle Mexican Grill in a small storefront in Denver. Although many other restaurants in the area served Mexican food, Ells took a somewhat different approach: The food was made entirely from locally grown fresh ingredients prepared in an “open kitchen” visible to his customers, and the menu was streamlined to focus on varieties of just two items, burritos and tacos. Ells’s approach has proven very successful. By 2015, the company had revenue of more than \$4 billion from its more than 1,800 restaurants, and it employed more than 50,000 workers. In fact, Chipotle is credited with having started a new category of restaurant—“fast casual.” Like Chipotle, fast-casual restaurants prepare fresh food quickly but do not offer table service. These restaurants offer food that many customers consider healthier because it is made with higher-quality ingredients than the food at Taco Bell and McDonald’s.

When we discussed the situation of firms in perfectly competitive markets in Chapter 12, we saw that these markets share three key characteristics:

1. There are many firms.
2. All firms sell identical products.
3. There are no barriers to new firms entering the industry.

The market Chipotle competes in shares two of these characteristics: There are many restaurants serving Mexican food, and the barriers to entering the market are very low. But the products that Chipotle and its competitors sell are *differentiated* rather than identical. So, the market for Mexican food is *monopolistically competitive* rather than perfectly competitive.

Can Chipotle continue to succeed? In 2015, the firm’s growth slowed more than expected and competitors, such as Qdoba and Moe’s Southwest Grill, that had adopted similar approaches to preparing and selling Mexican food were attracting some of Chipotle’s customers. As we will see, most monopolistically competitive firms are unable to earn an economic profit in the long run.

Economics in Your Life

Can You Operate a Successful Restaurant?

After you graduate, you plan to realize your dream of opening an Italian restaurant. You have many decisions to make in operating your restaurant. Will it be “family style,” with sturdy but inexpensive furniture, or will it be more elegant, with nice furniture, tablecloths, and candles? Will you offer a full menu or concentrate on pasta dishes that use your grandmother’s secret sauce? These and other decisions you make will distinguish your restaurant from competitors. What’s likely to happen in the restaurant market in your hometown after you open your restaurant? How successful are you likely to be? Try to answer these questions as you read this chapter. You can check your answers against those we provide on **page 519** at the end of this chapter.

Monopolistic competition A market structure in which barriers to entry are low and many firms compete by selling similar, but not identical, products.

Many markets in the U.S. economy are similar to the restaurant market: They have many buyers and sellers, and the barriers to entry are low, but the goods and services offered for sale are differentiated rather than identical. Examples of these markets include coffee houses, movie theaters, supermarkets, and clothing manufacturing. In fact, the majority of the firms you buy from are competing in **monopolistically competitive** markets.

We have seen how perfect competition benefits consumers and results in economic efficiency. Will these same desirable outcomes also hold for monopolistically competitive markets? This question is important because monopolistically competitive markets are common.

13.1 Demand and Marginal Revenue for a Firm in a Monopolistically Competitive Market

LEARNING OBJECTIVE: Explain why a monopolistically competitive firm has downward-sloping demand and marginal revenue curves.

If the Chipotle restaurant located a mile from where you live raises the price of a veggie burrito from \$7.00 to \$7.50, it will lose some, but not all, of its customers. Some customers will switch to buying their burritos at another restaurant, but other customers will be willing to pay the higher price for a variety of reasons: This restaurant may be closer to them, or they may prefer Chipotle's burritos to similar burritos at competing restaurants. So, a Chipotle restaurant will face a downward-sloping demand curve, unlike a wheat farmer who will sell no wheat if he raises his price and, therefore, faces a horizontal demand curve.

The Demand Curve for a Monopolistically Competitive Firm

Figure 13.1 shows how a change in price affects the quantity of burritos Chipotle sells. The increase in the price from \$7.00 to \$7.50 decreases the quantity of burritos sold from 3,000 per week to 2,400 per week.

[MyEconLab](#) [Concept Check](#)

Marginal Revenue for a Firm with a Downward-Sloping Demand Curve

For a firm in a perfectly competitive market, the demand curve and the marginal revenue curve are the same (see Chapter 12). A perfectly competitive firm faces a horizontal demand curve and does not have to cut the price to sell a larger quantity. A monopolistically competitive firm, however, must cut the price to sell more, so its marginal revenue curve will slope downward and will be below its demand curve.

The data in Table 13.1 illustrate this point. To keep the numbers simple, let's assume that your local Chipotle restaurant is very small and sells at most 11 burritos per week. If this Chipotle charges a price of \$10.00 or more, all of its potential customers will buy

[MyEconLab](#) [Animation](#)

Figure 13.1

The Downward-Sloping Demand Curve for Burritos at Chipotle

If a Chipotle restaurant increases the price of its burritos, it will lose some, but not all, of its customers. In this case, raising the price from \$7.00 to \$7.50 reduces the quantity of burritos sold from 3,000 to 2,400. Therefore, unlike a perfect competitor, a Chipotle restaurant faces a downward-sloping demand curve.

their burritos somewhere else. If it charges \$9.50, it will sell 1 burrito per week. For each additional \$0.50 this Chipotle reduces the price, it increases the number of burritos it sells by 1. The third column in the table shows how the firm's *total revenue* changes as it sells more burritos. The fourth column shows the firm's revenue per unit, or its *average revenue*. Average revenue is equal to total revenue divided by quantity. Because total revenue equals price multiplied by quantity, dividing by quantity leaves just price. Therefore, *average revenue is always equal to price*. This result will be true for firms selling in any of the four market structures (see Chapter 12).

The last column in Table 13.1 shows the firm's marginal revenue, or the change in total revenue as the firm sells 1 more burrito. For a perfectly competitive firm, the additional revenue received from selling 1 more unit is just equal to the price. That will *not* be true for this Chipotle because to sell another burrito, it has to reduce the price. When the firm cuts the price by \$0.50, one good thing happens, and one bad thing happens:

- **The good thing.** It sells 1 more burrito; we can call this the *output effect*.
- **The bad thing.** It receives \$0.50 less for each burrito that it could have sold at the higher price; we can call this the *price effect*.

Figure 13.2 illustrates what happens when the firm cuts the price from \$7.50 to \$7.00. Selling the sixth burrito adds the \$7.00 price to the firm's revenue; this is the

MyEconLab Animation

Figure 13.2

How a Price Cut Affects a Firm's Revenue

If a local Chipotle reduces the price of a burrito from \$7.50 to \$7.00, the number of burritos it sells per week will increase from 5 to 6. Its marginal revenue from selling the sixth burrito will be \$4.50, which is equal to the \$7.00 additional revenue from selling 1 more burrito (the area of the green rectangle) minus the \$2.50 loss in revenue from selling the first 5 burritos for \$0.50 less each (the area of the red rectangle).

MyEconLab Animation

Figure 13.3

The Demand and Marginal Revenue Curves for a Monopolistically Competitive Firm

Any firm that has the ability to affect the price of the product it sells will have a marginal revenue curve that is below its demand curve. We plot the data from Table 13.1 to create the demand and marginal revenue curves. After the tenth burrito, marginal revenue becomes negative because the additional revenue received from selling 1 more burrito is smaller than the revenue lost from receiving a lower price on the burrito that could have been sold at the original price.

output effect. But this Chipotle now receives a price of \$7.00, rather than \$7.50, on the first 5 burritos sold; this is the price effect. As a result of the price effect, the firm's revenue on these 5 burritos is \$2.50 less than it would have been if the price had remained at \$7.50. So, the firm has gained \$7.00 in revenue on the sixth burrito and lost \$2.50 in revenue on the first 5 burritos, for a net change in revenue of \$4.50. Marginal revenue is the change in total revenue from selling 1 more unit. Therefore, the marginal revenue of the sixth burrito is \$4.50. Notice that the marginal revenue of the sixth burrito is far below its price of \$7.00. In fact, for each additional burrito this Chipotle sells, marginal revenue will be less than price. There is an important general point: *Every firm that has the ability to affect the price of the good or service it sells will have a marginal revenue curve that is below its demand curve.* Only firms in perfectly competitive markets, which can sell as many units as they want at the market price, have marginal revenue curves that are the same as their demand curves.

Figure 13.3 shows the relationship between the demand curve and the marginal revenue curve for the local Chipotle. Notice that after the tenth burrito, marginal revenue becomes negative. This occurs because the additional revenue received from selling 1 more burrito is smaller than the revenue lost from receiving a lower price on the burritos that could have been sold at the original price.

13.2 How a Monopolistically Competitive Firm Maximizes Profit in the Short Run

LEARNING OBJECTIVE: Explain how a monopolistically competitive firm maximizes profit in the short run.

All firms use the same approach to maximize profit: They produce the quantity where marginal revenue is equal to marginal cost. So the local Chipotle will maximize profit by selling the quantity of burritos for which the last burrito sold adds the same amount to the firm's revenue as to its costs. Let's look more carefully at how monopolistically competitive firms maximize profit by considering the situation the local Chipotle faces in the short run. Recall that in the short run, at least one factor of production is fixed, and there is not enough time for new firms to enter the market (see Chapter 11). A Chipotle has many costs, including the cost of purchasing the ingredients for its burritos and other menu items, the electricity it uses, and the wages of its employees. Recall that a firm's *marginal cost* is the increase in total cost resulting from producing another unit of output. We have seen that for many firms, the marginal cost curve has

a U shape. We will assume that the marginal cost curve for this Chipotle has the usual shape.

We combine the revenue data for this Chipotle from Table 13.1 with cost data to create the table in Figure 13.4. The graphs in Figure 13.4 plot the data from the table. In panel (a), we see how this Chipotle can determine its profit-maximizing quantity and price. As long as the marginal cost of selling 1 more burrito is less than the marginal revenue, the firm should sell additional burritos. For example, increasing the quantity of burritos sold from 3 per week to 4 per week increases cost by \$5.00 but increases revenue by \$6.50. So, the firm's profits are increased by \$1.50 as a result of selling the fourth burrito.

As this Chipotle sells more burritos, rising marginal cost eventually equals marginal revenue, and the firm sells the profit-maximizing quantity of burritos. Marginal

Figure 13.4 Maximizing Profit in a Monopolistically Competitive Market

To maximize profit, a Chipotle restaurant wants to sell burritos up to the point where the marginal revenue from selling the last burrito is just equal to the marginal cost. As the table shows, selling the fifth burrito—point A in panel (a)—adds \$5.50 to the firm's costs and \$5.50 to its revenues. The firm then uses the demand curve to find the price that will lead

consumers to buy this quantity of burritos (point B). In panel (b), the green rectangle represents the firm's profits. The rectangle has a height equal to \$1.50, which is the \$7.50 price minus the average total cost of \$6.00, and it has a base equal to the quantity of 5 burritos. So, for this Chipotle profit equals $\$1.50 \times 5 = \7.50 .

cost equals marginal revenue with the fifth burrito, which adds \$5.50 to the firm's costs and \$5.50 to its revenues—point A in panel (a) of Figure 13.4. The demand curve tells us the price at which the firm is able to sell 5 burritos per week. In Figure 13.4, if we draw a vertical line from 5 burritos up to the demand curve, we can see that the price at which the firm can sell 5 burritos per week is \$7.50 (point B). We can conclude that for this Chipotle, the profit-maximizing quantity is 5 burritos, and the profit-maximizing price is \$7.50. If the firm sells more than 5 burritos per week, its profit will fall. For example, selling a sixth burrito adds \$6.00 to its costs and only \$4.50 to its revenues. So, its profit will fall from \$7.50 to \$6.00.

Panel (b) adds the average total cost curve for Chipotle. The panel shows that the average total cost of selling 5 burritos is \$6.00. Recall from Chapter 12 that:

$$\text{Profit} = (P - ATC) \times Q.$$

In this case, profit = $(\$7.50 - \$6.00) \times 5 = \$7.50$. The green rectangle in panel (b) shows the amount of profit. The rectangle has a base equal to Q and a height equal to $(P - ATC)$, so its area equals profit.

Notice that, unlike a perfectly competitive firm, which produces where $P = MC$, a monopolistically competitive firm produces where $P > MC$. In this case, this Chipotle is charging a price of \$7.50, although marginal cost is \$5.50. For a perfectly competitive firm, price equals marginal revenue, $P = MR$. Therefore, to fulfill the $MR = MC$ condition for profit maximization, a perfectly competitive firm will produce where $P = MC$. $P > MR$ for a monopolistically competitive firm because the firm's marginal revenue curve is below its demand curve. Therefore, a monopolistically competitive firm will maximize profits by producing where $P > MC$.

Does Minimizing Cost Maximize Profit at Apple?

Suppose Apple finds that the relationship between the average total cost of producing iPhones and the quantity of iPhones produced is as shown in the following graph.

Will Apple maximize profits if it produces 800,000 iPhones per month? Briefly explain.

Solving the Problem

- Step 1: Review the chapter material.** This problem is about how monopolistically competitive firms maximize profit, so you may want to review the section “How a Monopolistically Competitive Firm Maximizes Profit in the Short Run,” which begins on page 504.
- Step 2: Discuss the relationship between minimizing costs and maximizing profits.** Firms often talk about the steps they take to reduce costs. The graph shows that by producing 800,000 iPhones per month, Apple will minimize its average cost of production. But remember that minimizing cost is not the firm’s ultimate goal; the firm’s ultimate goal is to maximize profit. Depending on demand, a firm may maximize profit by producing a quantity that is either larger or smaller than the quantity that would minimize average total cost.
- Step 3: Draw a graph that shows Apple maximizing profit at a quantity where average cost is not minimized.** Note that in the graph, average total cost reaches a minimum at a quantity of 800,000, but profit is maximized at a quantity of 600,000.

13.3

What Happens to Profits in the Long Run?

LEARNING OBJECTIVE: Analyze the situation of a monopolistically competitive firm in the long run.

Remember that a firm makes an economic profit when its total revenue is greater than all of its costs, including the opportunity cost of the funds invested in the firm by its owners. Because cost curves include the owners’ opportunity costs, the Chipotle restaurant represented in Figure 13.4 on page 505 is making an economic profit. This economic profit gives entrepreneurs an incentive to enter this market and establish new firms. If a Chipotle is earning an economic profit selling burritos, new restaurants serving similar food are likely to open in the same area.

How Does the Entry of New Firms Affect the Profits of Existing Firms?

As new restaurants open near a local Chipotle, the firm’s demand curve will shift to the left. The demand curve will shift because the Chipotle will sell fewer burritos at each price when there are additional restaurants in the area selling food. The demand curve will also become more elastic because consumers have additional restaurants from which to buy

MyEconLab Animation

Figure 13.5 How Entry of New Firms Eliminates Profit

Panel (a) shows that in the short run, the local Chipotle faces the demand and marginal revenue curves labeled “Short run.” With this demand curve, Chipotle can charge a price above average total cost (point A) and make a profit, shown by the green rectangle. But this profit attracts new firms to

enter the market, which shifts the demand and marginal revenue curves to the curves labeled “Long run” in panel (b). Because price is now equal to average total cost (point B), Chipotle breaks even and no longer earns an economic profit.

burritos, so the Chipotle will lose more sales if it raises its prices. Figure 13.5 shows how the demand curve for the local Chipotle shifts as new firms enter its market.

In panel (a) of Figure 13.5, the short-run demand curve shows the relationship between the price of burritos and the quantity of burritos this Chipotle sells per week before the entry of new firms. With this demand curve, this Chipotle can charge a price above average total cost—shown as point A in panel (a)—and make a profit. But this profit attracts additional restaurants to the area and shifts the demand curve for this Chipotle’s burritos to the left. As long as this Chipotle is making an economic profit, there is an incentive for additional restaurants to open in the area, and the demand curve will continue shifting to the left. As panel (b) shows, eventually the demand curve will have shifted to the point where it is just touching—or tangent to—the average total cost curve.

In the long run, at the point where the demand curve is tangent to the average total cost curve, price is equal to average total cost (point B), the firm is breaking even, and it no longer earns an economic profit. In the long run, the demand curve is also more elastic because the more restaurants there are in the area, the more sales this Chipotle will lose to other restaurants if it raises its price.

Don't Let This Happen to You

Don't Confuse Zero Economic Profit with Zero Accounting Profit

Remember that economists count the opportunity cost of the owner’s investment in a firm as a cost. Suppose you invest \$200,000 opening a pizza parlor, and the return you could earn on those funds each year in a similar investment—such as opening a sandwich shop—is 10 percent. Therefore, the annual opportunity cost of investing the funds in your own business is 10 percent of \$200,000, or \$20,000. This \$20,000 is part of your profit

in the accounting sense, and you would have to pay taxes on it. But in an economic sense, the \$20,000 is a cost. In long-run equilibrium, we would expect that entry of new firms would keep you from earning more than 10 percent on your investment. So, you would end up breaking even and earning zero economic profit, even though you were earning an accounting profit of \$20,000.

Of course, it is possible that a monopolistically competitive firm will suffer an economic loss in the short run. As a consequence, the owners of the firm will not be covering the opportunity cost of their investment. We expect that, in the long run, firms will exit an industry if they are suffering an economic loss. If firms exit, the demand curve for the output of a remaining firm will shift to the right. This process will continue until the representative firm in the industry is able to charge a price equal to its average total cost and break even. Therefore, in the long run, monopolistically competitive firms will experience neither an economic profit nor an economic loss. Table 13.2 summarizes the short run and the long run for a monopolistically competitive firm.

Is a burrito healthier than the typical fast-food meal?

Is the Trend toward Healthy Eating a Threat to Chipotle's Market Niche?

A burger, French fries, and a soft drink. Or a pepperoni pizza with extra cheese. For generations, these were typical meals for many teenagers and young adults. Today, however, some people view these traditional fast-food meals as unhealthy. “Fast-casual” restaurants such as Chipotle have benefitted from that view. Chipotle advertises that it is committed “to sourcing the very best ingredients we can find and preparing them by hand.” The restaurant chain also notes that it prepares its food only with “vegetables grown in healthy soil, and pork from pigs allowed to freely root and roam outdoors or in deeply bedded barns.” Here’s how one news story summarized the appeal of fast-casual restaurants like Chipotle: They offer “food that’s fresh, wholesome and designed to move.” In an interview, Chipotle CEO Steve Ells said, “People understand that as a country, we are not as healthy as we should be, that a lot of our health issues are probably related to diet, and that we could be a lot healthier and happier if we just ate the right foods.”

Clearly, part of Chipotle’s appeal is that it offers a healthier alternative to traditional fast food such as burgers and pizza. So, an article in the *New York Times* showing that many restaurant meals, including those offered at Chipotle, had a lot of calories caused the firm’s management some concern. The U.S. Department of Agriculture recommends that adults consume between 1,600 and 2,400 calories per day, depending on their age, gender, and level of activity. For instance, a 20-year old woman who is moderately active can consume about 2,200 calories per day without gaining weight. According to the *New York Times* article, a single Chipotle meal of a carnitas burrito, chips and guacamole, and a Coke would amount to nearly that many calories.

Chipotle’s management argued that few of its customers ordered meals that were that high in calories. A followup *New York Times* article noted that data on online ordering gathered from the GrubHub Web site indicated that the typical meal ordered at Chipotle contained only 1,070 calories. But the data also showed that the typical Chipotle meal contained almost 100 percent of the recommended daily intake of salt and nearly 75 percent of the recommended intake of saturated fat. Another news story pointed out that a McDonald’s Big Mac might actually provide better nutrition than many of Chipotle’s burritos.

In competing against traditional fast-food restaurants such as McDonald’s and Domino’s, Chipotle has clearly benefitted from the view of many consumers that its meals are healthier than burgers, pizza, and traditional Mexican food served by fast-food restaurants like Taco Bell. Chipotle’s success in the market niche of fast-casual Mexican food seems to depend at least in part on whether consumers continue to view its meals as nutritious. Industry analysts are divided over whether these issues pose a significant threat to Chipotle’s continued success in its market niche.

Your Turn: Test your understanding by doing related problem 3.9 on page 523 at the end of this chapter.

Is Zero Economic Profit Inevitable in the Long Run?

The economic analysis of the long run shows the effects of market forces over time. Owners of monopolistically competitive firms, of course, do not have to passively accept this long-run result. The key to earning an economic profit is either to sell a differentiated product or to find a way of producing an existing product at a lower cost.

If a monopolistically competitive firm selling a differentiated product is earning a profit, the profit will attract the entry of additional firms, and the entry of those firms will eventually eliminate the firm's profit. If a firm introduces new technology that allows it to sell a good or service at a lower cost, competing firms will eventually duplicate that technology and eliminate the firm's profit. *But this result holds only if the firm stands still and fails to find new ways of differentiating its product or fails to find new ways of lowering the cost of producing its product.*

In 2015, Chipotle's growth began to slow as new competitors such as Qdoba and Moe's Southwest Grill entered its market and existing firms such as Taco Bell began to adopt similar menu items. In response, Chipotle's management took steps to increase its image as a healthier, more socially responsible alternative to its competitors. For instance, it announced that it was the first major restaurant chain to stop using genetically modified ingredients. It also publicized its buying more ingredients from local farms than any other restaurant chain. Firms continually struggle to find new ways of differentiating their products as they try to stay one step ahead of other firms that are attempting to copy their success.

The owner of a competitive firm is in a position like that of Ebenezer Scrooge in Charles Dickens's *A Christmas Carol*. When the Ghost of Christmas Yet to Come shows Scrooge visions of his own death, he asks the ghost, "Are these the shadows of the things that Will be, or are they shadows of things that May be, only?" The shadow of the end of their profits haunts owners of every firm. Firms try to continue earning a profit by reducing costs, by improving their products, by providing exceptional customer service, or by convincing consumers that their products are indeed different from what competitors offer. To stay one step ahead of its competitors, a firm has to offer consumers goods or services that they perceive to have greater *value* than those competing firms offer. Value can take the form of product differentiation that makes the good or service more suited to consumers' preferences, or it can take the form of a lower price.

Solved Problem 13.3

Buffalo Wild Wings Increases Costs to Increase Demand

In recent years, Buffalo Wild Wings has been very successful serving chicken wings and other inexpensive food in restaurants that feature large-screen televisions showing sporting events. Based in Minneapolis, the chain has in the past 10 years grown from 300 restaurants to more than 1,000. But competitors can easily copy this format, so CEO Sally Smith has adopted a strategy of spending heavily on a new layout for the restaurants aimed at attracting more lunch customers and more families. The layout has more natural light, larger televisions, and more of a sports stadium look than the previous layout. To renovate the restaurants, the

firm will incur a one-time cost of more than \$200 million. But increasing cost in the hope of increasing demand—and profit—is always risky.

Suppose that Smith's strategy fails to increase demand at her restaurants. What will be the effect on each of the following for a typical Buffalo Wild Wings restaurant: average total cost, average variable cost, average fixed cost, marginal cost, demand, and economic profit? Use a graph to illustrate your answer. Your graph should show the situation of the typical restaurant before and after the new strategy is implemented.

Solving the Problem

Step 1: Review the chapter material. This problem is about how a monopolistically competitive firm maximizes profit and how firms attempt to earn an economic profit in the long run, so you may want to review the section "How a Monopolistically Competitive Firm Maximizes Profit in the Short Run," which begins on page 504, and the section "Is Zero Economic Profit Inevitable in the Long Run?" which begins on page 510.

Step 2: Explain the effect of Smith's strategy on a Buffalo Wild Wings restaurant's costs, demand, and profit. If Smith's strategy fails to increase demand at her restaurants, then the demand curve for the typical Buffalo

Wild Wings restaurant will remain unchanged (rather than shifting to the right, as she hopes it will) because consumers will not view the restaurant any more favorably, and it will not be able to sell more chicken wings and other food at every price. Because the cost of the new layout is a one-time charge, it is an addition to the restaurant's fixed cost, so there is no effect on the restaurant's marginal cost or average variable cost, but the restaurant's average fixed cost and average total cost will both increase. Because the restaurant's cost will be increasing, while the demand for its chicken wings is unchanged, the restaurant's profit will decrease.

Step 3: Draw a graph to illustrate your argument. For simplicity, the graph assumes that chicken wings are the only item the restaurant sells. The demand curve and marginal revenue curves are unchanged, the average fixed cost curve shifts up from AFC_1 to AFC_2 , and the average total cost curve shifts up from ATC_1 to ATC_2 . The graph shows that the restaurant's profits are lower after the new strategy is implemented.

Extra Credit: As we have seen, firms constantly search for means of differentiating themselves from their competitors. Often, differentiation works for a while but then breaks down as competitors copy the strategy. In 2015, as Smith was implementing her new strategy, she was attempting to offset the effects of similar restaurants entering into the market. There were questions, though, as to whether the new approach featuring much larger televisions would necessarily appeal to families, one of Smith's key targets. Like CEOs of other monopolistically competitive firms, Smith knew that without innovating, her firm's profit would eventually be competed away by other firms, so she was willing to take the risk that increased spending on renovating her restaurants would increase demand enough to increase profit, despite the increase in cost. This problem shows that it was possible for her strategy to actually result in a lower profit.

13.4 Comparing Monopolistic Competition and Perfect Competition

LEARNING OBJECTIVE: Compare the efficiency of monopolistic competition and perfect competition.

We have seen that monopolistic competition and perfect competition share the characteristic that in long-run equilibrium, firms earn zero economic profit. As Figure 13.6 shows, however, there are two important differences between long-run equilibrium in the two markets:

- Monopolistically competitive firms charge a price greater than marginal cost.
- Monopolistically competitive firms do not produce at minimum average total cost.

Excess Capacity under Monopolistic Competition

Recall that a firm in a perfectly competitive market faces a perfectly elastic demand curve that is also its marginal revenue curve. Therefore, the firm maximizes profit by producing the quantity where price equals marginal cost. As panel (a) of Figure 13.6 shows, in long-run equilibrium, a perfectly competitive firm produces at the minimum point of its average total cost curve.

Panel (b) of Figure 13.6 shows that the profit-maximizing level of output for a monopolistically competitive firm comes at a level of output where price is greater than marginal cost, and the firm is not at the minimum point of its average total cost curve. A monopolistically competitive firm has *excess capacity*: If it increased its output, it could produce at a lower average total cost.

MyEconLab Concept Check

MyEconLab Animation

Figure 13.6 Comparing Long-Run Equilibrium under Perfect Competition and Monopolistic Competition

In panel (a), a perfectly competitive firm in long-run equilibrium produces at Q_{PC} , where price equals marginal cost, and average total cost is at a minimum. The perfectly competitive firm is both allocatively efficient and productively efficient. In panel (b), a monopolistically competitive firm produces at Q_{MC} , where price is greater than marginal cost, and average

total cost is not at a minimum. As a result, the monopolistically competitive firm is neither allocatively efficient nor productively efficient. The monopolistically competitive firm has excess capacity equal to the difference between its profit-maximizing level of output and the productively efficient level of output.

Is Monopolistic Competition Inefficient?

We previously discussed the difference between productive efficiency and allocative efficiency (see Chapter 12).

- *Productive efficiency* refers to the situation where a good is produced at the lowest possible cost. For productive efficiency to hold, firms must produce at the minimum point of the average total cost curve.
- *Allocative efficiency* refers to the situation where every good or service is produced up to the point where the last unit provides a marginal benefit to consumers equal to the marginal cost of producing it. For allocative efficiency to hold, firms must charge a price equal to marginal cost.

In a perfectly competitive market, both productive efficiency and allocative efficiency are achieved, but in a monopolistically competitive market, neither is achieved. Does it matter? Economists have debated whether monopolistically competitive markets being neither productively nor allocatively efficient results in a significant loss of well-being to society in these markets compared with perfectly competitive markets.

[MyEconLab](#) [Concept Check](#)

How Consumers Benefit from Monopolistic Competition

Looking again at Figure 13.6, you can see that the key difference between the monopolistically competitive firm and the perfectly competitive firm is that the demand curve for the monopolistically competitive firm slopes downward, while the demand curve for the perfectly competitive firm is a horizontal line. The demand curve for the monopolistically competitive firm slopes downward because the good or service the firm is selling is differentiated from those being sold by competing firms. The perfectly competitive firm is selling a good or service identical to those being sold by its competitors. Remember that *firms differentiate their products to appeal to consumers*. For example, when Chipotle restaurants begin offering chicken and pork chorizo burritos, when Apple begins selling smartphones with larger screens, when General Mills introduces Apple-Cinnamon Cheerios, or when PepsiCo introduces Diet Wild Cherry Pepsi, they are all attempting to attract and retain consumers through product differentiation. The success of these product differentiation strategies indicates that some consumers find these products preferable to the alternatives. Consumers, therefore, are better off than they would have been had these companies not differentiated their products.

We can conclude that consumers face a trade-off when buying the product of a monopolistically competitive firm: They are paying a price that is greater than marginal cost, and the product is not being produced at minimum average cost, but they benefit from being able to purchase a product that is differentiated and more closely suited to their tastes.

Are All Cupcakes the Same?

The more basic a product, the more difficult you would expect it to be for an entrepreneur to differentiate her product enough from competitors to earn an economic profit, even in the short run. Mia Bauer was able to pull off this difficult feat when she convinced many consumers that she had developed a very different variety of a familiar product—the cupcake.

In 2002, Mia Bauer could find cupcakes only in basic flavors—strawberry, vanilla, and chocolate—in most bakeries and supermarkets. She thought that consumers might prefer the more elaborate cupcakes she baked; cupcakes such as Caramel Macchiato, which is a chocolate cupcake filled with caramel and topped with a frosting of coffee cream cheese. Rather than sell the cupcakes to bakeries or supermarkets, Mia and her husband Jason decided to open their own gourmet cupcake store, Crumbs Bake Shop, in New York City. At the time, there were only three other stores in the United States

devoted exclusively to selling cupcakes. The Bauers believed that their cupcakes were so much tastier than other cupcakes that consumers would be willing to pay the relatively high price of \$3.75 for a single cupcake. Initially, the Bauers' gamble paid off, and their store was profitable. They eventually expanded by opening 63 cupcake stores in 10 states.

But an entrepreneur can easily open a new cupcake store, which makes the barriers to entering the retail cupcake industry low. By 2013, many entrepreneurs had opened cupcake stores to compete with the Bauers. Many of these stores offered gourmet cupcakes very similar to the Bauers' cupcakes—but at lower prices. When asked how he could compete with these new entrants, John Bauer said, “Everybody sells cupcakes and will continue to do so, [but] we’re building a nationally recognizable brand.”

A nationally recognizable brand wasn't enough, however, and by late 2013, falling sales led the Bauers to close 10 stores. Sales continued to fall, and in July 2014, the Bauers closed all of their remaining stores and declared bankruptcy. A few months later, new owners assumed control of the firm and reopened some of the stores—with a new menu much less focused on cupcakes. The head of a market research firm commented that to succeed, the new owners “need to ... convince people that the new products are going to be different in some way.”

Unfortunately for the Bauers, while consumers may not believe that all cupcakes are the same, they apparently didn't believe that cupcakes from Crumbs Bake Shop were significantly different from other cupcakes.

13.5

How Marketing Differentiates Products

LEARNING OBJECTIVE: Define marketing and explain how firms use marketing to differentiate their products.

Firms can differentiate their products through **marketing**, which refers to all the activities necessary for a firm to sell a product to a consumer. Marketing includes activities such as determining which product to sell, designing the product, advertising the product, deciding how to distribute the product—for example, in retail stores or through a Web site—and monitoring how changes in consumer tastes are affecting the market for the product. Peter F. Drucker, a leading business strategist, described marketing as follows: “It is the whole business seen from the point of view of its final result, that is, from the consumer’s point of view. . . . True marketing . . . does not ask, ‘What do we want to sell?’ It asks, ‘What does the consumer want to buy?’”

For monopolistically competitive firms to earn an economic profit and defend the profit from competitors, they must differentiate their products. Firms use two marketing tools to differentiate their products: brand management and advertising.

Brand Management

Once a firm has succeeded in differentiating its product, it must try to maintain that differentiation over time through **brand management**. As we have seen, whenever a firm successfully introduces a new product or a significantly different version of an old

Marketing All the activities necessary for a firm to sell a product to a consumer.

Brand management The actions of a firm intended to maintain the differentiation of a product over time.

product, it earns an economic profit in the short run. But the success of the firm inspires competitors to copy the new or improved product, and, in the long run, the firm's economic profit will be competed away. Firms use brand management to postpone the time when they will no longer be able to earn an economic profit. **MyEconLab** Concept Check

Advertising

An innovative advertising campaign can make even long-established and familiar products, such as Coke or McDonald's Big Mac hamburgers, seem more desirable than competing products. When a firm advertises a product, it is trying to shift the demand curve for the product to the right and to make it more inelastic. If the firm is successful, it will sell more of the product at every price, and it will be able to increase the price it charges without losing as many customers. Of course, advertising also increases a firm's costs. If the increase in revenue that results from the advertising is greater than the increase in costs, the firm's profit will increase. **MyEconLab** Concept Check

Defending a Brand Name

Once a firm has established a successful brand name, it has a strong incentive to defend it. A firm can apply for a *trademark*, which grants legal protection against other firms using its product's name.

One threat to a trademarked name is the possibility that it will become so widely used for a type of product that it will no longer be associated with the product of a specific company. Courts in the United States have ruled that when this happens, a firm is no longer entitled to legal protection of the brand name. For example, "aspirin," "escalator," and "thermos" were originally all brand names of the products of particular firms, but each became so widely used to refer to a type of product that none remains a legally protected brand name. Firms spend substantial amounts of money trying to prevent this from happening. Coca-Cola, for example, employs people to travel to restaurants around the country and order a "Coke" with their meal. If the restaurant serves Pepsi or some other cola, rather than Coke, Coca-Cola's legal department sends the restaurant a letter reminding the owner that "Coke" is a trademarked name and not a generic name for any cola. Similarly, Xerox Corporation spends money on advertising to remind the public that "Xerox" is not a generic term for making photocopies.

Legally enforcing trademarks can be difficult. Estimates are that each year, U.S. firms lose hundreds of billions of dollars in sales worldwide as a result of unauthorized use of their trademarked brand names. U.S. firms often find it difficult to enforce their trademarks in the courts of some foreign countries, although recent international agreements have increased the legal protections for trademarks.

Firms that sell their products through franchises rather than through company-owned stores encounter the problem that if a franchisee does not run his or her business well, the firm's brand may be damaged. Firms can take steps to keep such damage from happening. For example, automobile firms send "roadmen" to visit their dealers to make sure the dealerships are clean and well maintained and that the service departments employ competent mechanics and are well equipped with spare parts. Similarly, McDonald's sends employees from corporate headquarters to visit McDonald's franchises to make sure the bathrooms are clean and the French fries are hot. **MyEconLab** Concept Check

What Makes a Firm Successful?

LEARNING OBJECTIVE: Identify the key factors that determine a firm's success.

A firm's owners and managers control some of the factors that make a firm successful and allow it to earn economic profits. The most important of these is the firm's ability to differentiate its product or to produce it at a lower average cost than competing firms. A firm that successfully does one or both of these things creates *value* for its

MyEconLab Animation

Figure 13.7 What Makes a Firm Successful?

The factors under a firm's control—the ability to differentiate its product and the ability to produce it at lower cost—combine with the factors beyond its control to determine the firm's profitability.

customers. Consumers will buy a product if they believe it meets a need not met by competing products or if its price is below that of competitors.

Some factors that affect a firm's profitability are not directly under the firm's control. Certain factors will affect all the firms in a market. For example, rising prices for jet fuel will reduce the profitability of all airlines. When many consumers decided that rather than buy DVDs, they preferred to download or stream movies from Netflix, iTunes, or Amazon, the profitability of all stores selling DVDs was reduced.

Sheer chance also plays a role in business, as it does in all other aspects of life. A struggling McDonald's franchise may see profits increase dramatically after the county unexpectedly decides to build a new road nearby. Many businesses in New York City, including restaurants, hotels, and theaters, experienced a marked drop in customers and profits as a result of the effects of Hurricane Sandy in October 2012. Figure 13.7 illustrates the important point that factors within the firm's control and factors outside the firm's control interact to determine the firm's profitability.

Is Being the First Firm in the Market a Key to Success?

Some business analysts argue that the first firm to enter a market can have important *first-mover advantages*. By being the first to sell a particular good, a firm may find its name closely associated with the good in the public's mind, as, for instance, Amazon is closely associated with ordering books online or eBay is associated with online auctions. This close association may make it more difficult for new firms to enter the market and compete against the first mover.

Surprisingly, though, recent research has shown that the first firm to enter a market often does *not* have a long-lived advantage over later entrants. Consider, for instance, the market for pens. Until the 1940s, the only pens available were fountain pens that had to be refilled frequently from an ink bottle and used ink that dried slowly and smeared easily. In October 1945, entrepreneur Milton Reynolds introduced the first ballpoint pen, which did not need to be refilled. When it went on sale at Gimbel's department store in New York City, it was an instant success. Although the pen had a price of \$12.00—the equivalent of about \$155.00 at today's prices—hundreds of thousands were sold, and Milton Reynolds became a millionaire.

Although not first to market, Bic ultimately was more successful than the firm that pioneered ballpoint pens.

Unfortunately, it didn't last. Although Reynolds had guaranteed that his pens would write for two years—later raised to five years—in fact, the pens often leaked and frequently stopped writing after only limited use. Sales began to collapse, the flood of pens returned under the company's guarantee wiped out its profit, and within a few years, Reynolds International Pen Company stopped selling pens in the United States. By the late 1960s, firms such as Bic, selling inexpensive—but reliable—ballpoint pens, dominated the market.

What happened to the Reynolds International Pen Company turns out to be more the rule than the exception. For example, Apple's iPod was not the first digital music player to appear on the U.S. market. Both SeaHans' MPMan and Diamond's PMP300 were released in the United States in 1998, three years before the iPod. Similarly, although Hewlett-Packard currently leads the market for laser printers, with a market share of more than 35 percent, it did not invent the laser printer. Xerox invented the laser printer, and IBM sold the first commercial laser printers, although neither firm is important in the market today. As another example, Procter & Gamble was not the first firm to sell disposable diapers when it introduced Pampers in 1961. Microsoft's Internet Explorer was not the first Web browser: Before Internet Explorer, there was Netscape; before Netscape, there was Mosaic; and before Mosaic, there were several other Web browsers that for a time looked as if they might dominate the market. As we saw in Chapter 3, in 2004 Microsoft introduced the SPOT smartwatch, but the company discontinued it in 2008 when it failed to find many buyers. In all these cases, the firms that were first to introduce a product ultimately lost out to other companies that arrived on the scene later but did a better job of providing consumers with products that were more reliable, less expensive, more convenient or that otherwise provided greater value.

Economics in Your Life

Can You Operate a Successful Restaurant?

At the beginning of the chapter, we asked you to think about how successful you are likely to be in opening an Italian restaurant in your hometown. As you saw in this chapter, if your restaurant is successful, other people are likely to open competing restaurants, and all your economic profit will eventually disappear. Your new competitors will sell Italian food, but it won't be exactly like yours. Each restaurant will have its own ideas on how best to appeal to people who like Italian food. Unless your food is very different from your competitors' food—or your service is much better—in the long run, you will be unable to charge prices high enough to allow you to earn an economic profit.

In a monopolistically competitive market, free entry will reduce prices and lead to zero economic profit in the long run. In addition to lowering prices, competition benefits consumers by leading firms to offer somewhat different versions of the same product; for example, two Italian restaurants will rarely be exactly alike.

Conclusion

In this chapter, we applied to the more common market structure of monopolistic competition many of the ideas about competition we developed in discussing perfect competition. At the end of Chapter 12, we concluded: “The competitive forces of the market impose relentless pressure on firms to produce new and better goods and services at the lowest possible cost. Firms that fail to adequately anticipate changes in consumer tastes or that fail to adopt the latest and most efficient production technology do not survive in the long run.” These conclusions are as true for fast-casual restaurants and firms in other monopolistically competitive markets as they are for wheat farmers and cage-free egg farmers in perfectly competitive markets.

In next two chapters, we discuss the remaining market structures: oligopoly and monopoly.

Demand and Marginal Revenue for a Firm in a Monopolistically Competitive Market, pages 502–504

LEARNING OBJECTIVE: Explain why a monopolistically competitive firm has downward-sloping demand and marginal revenue curves.

Summary

A firm competing in a **monopolistically competitive** market sells a differentiated product. Therefore, unlike a firm in a perfectly competitive market, it faces a downward-sloping demand curve. When a monopolistically competitive firm cuts the price of its product, it sells more units but must accept a lower price on the units it could have sold at the higher price. As a result, its marginal revenue curve is downward sloping. Every firm that has the ability to affect the price of the good or service it sells will have a marginal revenue curve that is below its demand curve.

Snow Skiing Lessons per Day (Q)	Price (P)	Total Revenue ($TR = P \times Q$)	Average Revenue ($AR = \frac{TR}{Q}$)	Marginal Revenue ($MR = \frac{\Delta TR}{\Delta Q}$)
0	\$80.00			
1	75.00			
2	70.00			
3	65.00			
4	60.00

7	45.00			
8	40.00			

- 1.7 Suppose you are analyzing a market with a large number of active firms. What would you look for in order to determine whether those firms face a downward sloping demand curve or a horizontal demand curve?
- 1.8 Is it possible for marginal revenue to be negative for a firm selling in a perfectly competitive market? Is it possible for marginal revenue to be negative for a firm selling in a monopolistically competitive market? Briefly explain.
- 1.9 In the graph on the following page, consider the marginal revenue of the eleventh unit sold. When the firm cuts the price from \$5.00 to \$4.75 to sell the eleventh unit, what area in the graph denotes the output effect, and what is the dollar value of the output effect? What area in the graph denotes the price effect, and what is the dollar value of the price effect? What is the marginal revenue of the eleventh unit?

- 1.10** Sally runs a vegetable stand. The following table shows two points on the demand curve for the heirloom tomatoes she sells:

Price	Quantity Demanded per Week
\$5.00	100,000
\$3.25	200,000

- What would Sally's marginal revenue be from lowering the price of tomatoes from \$5.00 to \$3.25?
- Calculate the output effect and the price effect from lowering the price to \$3.25.

13.2

How a Monopolistically Competitive Firm Maximizes Profit in the Short Run, pages 504–507

LEARNING OBJECTIVE: Explain how a monopolistically competitive firm maximizes profit in the short run.

Summary

A monopolistically competitive firm maximizes profit at the level of output where marginal revenue equals marginal cost. Price equals marginal revenue for a perfectly competitive firm, but price is greater than marginal revenue for a monopolistically competitive firm. Therefore, unlike a perfectly competitive firm, which produces where $P = MC$, a monopolistically competitive firm produces where $P > MC$.

Review Questions

- Why doesn't a monopolistically competitive firm produce where $P = MC$, as a perfectly competitive firm does?
- Stephen runs a pet salon. He is currently grooming 125 dogs per week. If instead of grooming 125 dogs, he grooms 126 dogs, he will add \$68.50 to his costs and \$60.00 to his revenues. What will be the effect on his profit of grooming 126 dogs instead of 125 dogs?
- Do you think a monopolistically competitive firm would be able to make a profit by producing a quantity that ensures that its marginal revenue equals its marginal cost?

Problems and Applications

- Josef manages a kebab shop in Sydney's central business district and has the following information on the shop's demand and costs:

Kebabs sold per Hour (Q)	Price (P)	Total Cost (TC)
0	\$6.00	\$3.00
1	5.50	7.00
2	5.00	10.00
3	4.50	12.50
4	4.00	14.50
5	3.50	16.00
6	3.00	17.00
7	2.50	18.50
8	2.00	21.00

- To maximize profit, how many kebabs should Josef sell per hour, what price should he charge, and how much profit will he make?
 - What is the marginal revenue Josef receives from selling the profit-maximizing quantity of kebabs? What is the marginal cost of producing the profit-maximizing quantity of kebabs?
- 2.5** (Related to Solved Problem 13.2 on page 506) Suppose a firm producing table lamps has the following costs:

Quantity	Average Total Cost
1,000	\$15.00
2,000	9.75
3,000	8.25
4,000	7.50
5,000	7.75
6,000	8.50
7,000	9.75
8,000	10.50
9,000	12.00

Ben and Jerry are managers at the company, and they have this discussion:

Ben: We should produce 4,000 lamps per month because that will minimize our average cost.

Jerry: But shouldn't we maximize profit rather than minimize cost? To maximize profit, don't we need to take demand into account?

Ben: Don't worry. By minimizing average cost, we will be maximizing profit. Demand will determine how high the price we can charge will be, but it won't affect our profit-maximizing quantity.

Evaluate the discussion between the two managers.

Draw a graph showing the effect of this increase on the price of Vapiano's pizza and on the quantity of pizzas Vapiano sells. Be sure that your graph includes Vapiano's demand, marginal revenue, marginal cost, and average total cost curves. Your graph should show any resulting changes in the curves.

- 2.7** William Germano previously served as the vice president and publishing director at the Routledge publishing company. He once gave the following description of how a publisher might deal with an unexpected increase in the cost of publishing a book:

It's often asked why the publisher can't simply raise the price [if costs increase]. . . . It's likely that the editor [is already] . . . charging as much as the market will bear. . . . In other words, you might be willing to pay \$50.00 for a . . . book on the Brooklyn Bridge, but if . . . production costs [increase] by 25 percent, you might think \$62.50 is too much to pay, though that would be what the publisher needs to charge. And indeed the publisher may determine that \$50.00 is this book's ceiling—the most you would pay before deciding to rent a movie instead.

- According to what you have learned in this chapter, how do firms adjust the price of a good when there is an increase in cost? Use a graph to illustrate your answer.
- Does the model of monopolistic competition seem to fit Germano's description? If a publisher does not raise the price of a book following an increase in its production cost, what will be the result?
- How would the elasticity of demand for published books affect the ability of the publishing company to raise book prices when costs increase?

- 2.8** In 1916, Ford Motor Company produced 500,000 Model T Fords, at a price of \$440 each. The company made a profit of \$60 million that year. Henry Ford told a newspaper reporter that he intended to reduce the price of the Model T to \$360, and he expected to sell 800,000 cars at that price. Ford said, "Less profit on each car, but more cars, more employment of labor, and in the end we get all the total profit we ought to make."

- Did Ford expect the total revenue he received from selling Model Ts to rise or fall following the price cut?
- Use the information given above to calculate the price elasticity of demand for Model Ts. Use the midpoint formula to make your calculation. (See Chapter 6, page 244, if you need a refresher on the midpoint formula.)
- What would the average total cost of producing 800,000 Model Ts have to be for Ford to make as much profit selling 800,000 Model Ts as it made selling 500,000 Model Ts? Is this smaller or larger than the average total cost of producing 500,000 Model Ts?
- Assume that Ford would make the same total profit when selling 800,000 cars as when selling 500,000 cars. Was Henry Ford correct in saying he would make less profit per car when selling 800,000 cars than when selling 500,000 cars?

13.3 What Happens to Profits in the Long Run? pages 507–512

LEARNING OBJECTIVE: Analyze the situation of a monopolistically competitive firm in the long run.

Summary

If a monopolistically competitive firm earns an economic profit in the short run, entry of new firms will eliminate the profit in the long run. If a monopolistically competitive firm is suffering an economic loss in the short run, exit of existing firms will eliminate the loss in the long run. Monopolistically competitive firms continually struggle to find new ways of differentiating their products as they try to stay one step ahead of other firms that are attempting to copy their success.

Review Questions

- 3.1 What effect does the entry of new firms have on the economic profit of existing firms?
- 3.2 Why does the entry of new firms cause the demand curve of an existing firm in a monopolistically competitive market to shift to the left and to become more elastic?
- 3.3 What is the difference between zero accounting profit and zero economic profit?
- 3.4 Would a perfectly competitive market prove more stable than a monopolistically competitive one in the long run? What happens to their profits in the long run?

Problems and Applications

- 3.5 (Related to the Chapter Opener on page 501) Chipotle Mexican Grill restaurants have been a very popular “fast-casual” dining option—with better food choices than fast-food restaurants like McDonald’s and faster service and lower prices than traditional restaurants. Chipotle’s profit per restaurant is much greater than McDonald’s. Ten years from now, would you expect Chipotle’s economic profit per restaurant to be higher, lower, or about the same as they are today? Briefly explain.
- 3.6 Suppose Angelica opens a small store near campus, selling beef brisket sandwiches. Use the graph below, which

shows the demand and cost for Angelica’s beef brisket sandwiches, to answer the following questions.

- a. If Angelica wants to maximize profit, how many beef brisket sandwiches should she sell per day, and what price should she charge? Briefly explain your answer.
- b. How much economic profit (or loss) is Angelica earning? Briefly explain.
- c. Is Angelica likely to continue selling this number of beef brisket sandwiches in the long run? Briefly explain.

3.7 (Related to the Don’t Let This Happen to You on page 508)

A student remarks:

If firms in a monopolistically competitive industry are earning an economic profit, new firms will enter the industry. Eventually, a representative firm will find that its demand curve has shifted to the left, until it is just tangent to its average total cost curve and it is earning zero profit. Because firms are earning zero profit at that point, some firms will leave the industry, and the representative firm will find that its demand curve will shift to the right. In long-run equilibrium, price will be above average total cost by just enough so that each firm is just breaking even.

Briefly explain whether you agree with this analysis.

- 3.8 Competition from Amazon and other online booksellers has resulted in some brick-and-mortar bookstores suffering losses. According to a news story, over the past 9 years, the number of bookstores in British cities has declined by one-third. Draw a graph showing the effect on the remaining bookstores of the exit of many competitors from this industry. Be sure that your graph includes the bookstore’s demand, marginal revenue, marginal cost, and average total cost curves. Your graph should show changes in any of the curves. Your graph should also show any changes in the area representing the store’s economic profit (or loss). Be sure to explain any assumptions you are making.

An article in the *New York Times* describes Chipotle as “the restaurant chain that has come to symbolize the tastes of the millennial generation” and lists the sources of Chipotle’s success as including the restaurant’s allowing “their customers to tailor their meals, and still have them ready in a flash ... playing to consumer tastes for customization, speed and ingredients from sources that adhere to animal welfare, organic and other standards.” Are these attributes likely to ensure that Chipotle will earn an economic profit in the long run? 3.10 (Related to Solved Problem 13.3 on page 511) In 2015, analysts at the Goldman Sachs investment bank were optimistic that Buffalo Wild Wings would increase its profit over the next few years. They cited two factors as favorable to the chain's profitability: The chain's "greater pricing power allows them to easily implement menu changes to take advantage of [changes in] consumer preferences" and "the opportunity for the chain to grow as a lunch destination."

- What do the analysts mean by the chain's greater pricing power? Is Buffalo Wild Wings likely to be able to sustain this greater pricing power in the long run? Briefly explain.
- Why might doing additional business at lunchtime be particularly likely to add to the profit that Buffalo Wild Wings earns? Would this additional lunchtime business result in the chain's earning an economic profit in the long run? Briefly explain.

3.11 Michael Korda was, for many years, editor-in-chief at the Simon & Schuster book publishing company. He has written about the many books that have become bestsellers by promising to give readers financial advice that will make them wealthy, by, for example, buying and selling real estate. Korda is skeptical about the usefulness of the advice in these books because "I have yet to meet anybody who got rich by buying a book, though quite a few

people got rich by writing one." On the basis of the analysis in this chapter, discuss why it may be very difficult to become rich by following the advice found in a book.

3.12 An article in the *Wall Street Journal* reported that Western European brewers such as Heineken, Carlsberg, and Anheuser-Busch InBev are increasing their production and marketing of nonalcoholic beer. The article quotes a Carlsberg executive for new-product development as saying:

Nonalcoholic beer is a largely unexploited opportunity for big brewers. It is quite a natural move when you see that the overall beer market [in Western Europe is] going down. So, of course, we're battling for market share.

The article further states that "brewers are hoping to capitalize on health consciousness" and that "recent brewing advances are helping improve the taste of nonalcoholic beers."

- In what sense is nonalcoholic beer an "unexploited opportunity" for big brewers?
- Are the brewers responding to consumer desires, or are brewers exploiting consumers? Briefly explain.
- How will the "recent brewing advances" that improve taste affect the market for nonalcoholic beer?

13.4 Comparing Monopolistic Competition and Perfect Competition, pages 513–515

LEARNING OBJECTIVE: Compare the efficiency of monopolistic competition and perfect competition.

Summary

Perfectly competitive firms produce at a quantity where price equals marginal cost and at minimum average total cost. Perfectly competitive firms achieve both allocative and productive efficiency. Monopolistically competitive firms produce at a quantity where price is greater than marginal cost and above minimum average total cost. Monopolistically competitive firms do not achieve either allocative or productive efficiency. Consumers face a trade-off when buying the product of a monopolistically competitive firm: They are paying a price that is greater than marginal cost, and the product is not being produced at minimum average total cost, but they benefit from being able to purchase a product that is differentiated and more closely suited to their tastes.

Review Questions

- Are long-run profits equal to zero only when firms charge a price equal to their marginal cost, and produce an average total cost-minimizing quantity of output? Briefly explain.

- What are the implications of monopolistically competitive firms having excess capacity?
- Why is a monopolistically competitive firm not allocatively efficient?
- Does the fact that monopolistically competitive markets are not allocatively or productively efficient mean that there is a significant loss in economic well-being to society in these markets? In your answer, be sure to define what you mean by "economic well-being."

Problems and Applications

- A student makes the following comment:

I can understand why a perfectly competitive firm won't earn a profit in the long run because it charges a price equal to marginal cost. But a monopolistically competitive firm can charge a price greater than marginal cost, so why can't it continue to earn a profit in the long run?

How would you answer this question?

4.6 Consider the following graph:

- Is it possible to say whether this firm is a perfectly competitive firm or a monopolistically competitive firm? If so, explain how you are able to make this determination.

4.9 In recent years, consumers have been less willing to buy packaged foods that contain gluten or high levels of fat and salt or soft drinks containing sugar. Firms such as General Mills, Kellogg, and Coca-Cola have responded by modifying many of their products by, for example, making them gluten-free and eliminating or reducing salt, sugar, and artificial flavors and colors. General Mills Chief Executive Officer Ken Powell explained, "The reality of the changing food values of our consumers is central to what we're doing." Monopolistically competitive firms do not achieve productive efficiency or allocative efficiency, but economists argue that consumers benefit when these firms differentiate their products to appeal to consumers. How Marketing Differentiates Products, pages 515–516

LEARNING OBJECTIVE: Define marketing and explain how firms use marketing to differentiate their products.

Summary

Marketing refers to all the activities necessary for a firm to sell a product to a consumer. Firms use two marketing tools to differentiate their products: brand management and advertising.

Brand management refers to the actions of a firm intended to maintain the differentiation of a product over time. When a firm

has established a successful brand name, it has a strong incentive to defend it. A firm can apply for a *trademark*, which grants legal protection against other firms using its product's name.

13.6 What Makes a Firm Successful? pages 516–518

13.6 LEARNING OBJECTIVE: Identify the key factors that determine a firm's success.

Summary

A firm's owners and managers control some of the factors that determine the profitability of the firm. Other factors affect all the firms in the market or result from chance, so they are not under the control of the firm's owners. The interactions between factors the firm controls and factors it does not control determine its profitability.

Apple, Spotify, and the Music Streaming Revolution

Few industries have experienced the disruptive force of technology the way the music industry has. For decades prior to the 1990s, large recording companies such as Universal Music Group, EMI, Warner Music, and Columbia dominated the music industry.

By the mid-1990s, though, the music industry faced a serious threat as people started to download songs from the Internet. MP3 files compressed standard music files to be small enough to make downloading songs from the Internet feasible. Many people were buying CDs, converting the songs on them to MP3 files, and posting the songs to the Internet, where they were available for anyone to download for free, in violation of the copyright laws.

In 2001, Apple introduced the iPod, the first successful portable MP3 player. As CD sales declined sharply, most record companies became willing to sell music in Apple's iTunes store, which opened in 2003 and allowed people to legally download millions of songs for \$0.99 each. Although Apple gave the record companies a 70 percent share of the revenue from downloads, that didn't come close to replacing what the record companies and musicians were losing from the collapse of CD sales.

Apple's iTunes was tremendously successful, but it did not put an end to digital piracy. By 2015, many consumers were switching from buying individual songs to

streaming songs from YouTube or other sites without purchasing them. Several companies offered plans that allowed people to stream for free, although with advertisements similar to those on commercial radio stations. Spotify, a music streaming service based in Sweden, offered a subscription plan that allowed unlimited streaming for \$9.99 per month without advertisements. In 2015, Apple began offering Apple Music, in direct competition with Spotify.

An industry like music streaming that includes only a few firms is an *oligopoly*. In an oligopoly, a firm's profitability depends on its interactions with other firms. In these industries, firms must develop *business strategies*, which involve not just deciding what price to charge and how many units to produce but also how much to advertise, which new technologies to adopt, how to manage relations with suppliers, and which new markets to enter.

Because there are relatively few firms competing in an oligopolistic industry, each firm must continually react to other firms' actions or risk a substantial decline in sales. In this chapter, we focus on strategic interactions among firms.

Economics in Your Life

Why Can't You Find a Cheap PlayStation 4?

You and your roommates have just moved into a great apartment and decide to treat yourselves to a PlayStation 4 game system—provided that you can find one at a relatively low price. You check Amazon, Best Buy, and Target and find a price of \$399.99 at all three. Finally, you check Walmart, and you find a lower price: \$399.00, a whopping discount of \$0.99. Why isn't one of these big retailers willing to charge a lower price? What happened to price competition? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 549** at the end of this chapter.

In studying perfectly competitive and monopolistically competitive industries, our analysis focused on how to determine a firm's profit-maximizing price and quantity. We concluded that firms maximize profit by producing where marginal revenue equals marginal cost. To determine marginal revenue and marginal cost, we used graphs that included the firm's demand, marginal revenue, and marginal cost curves. In this chapter, we will study oligopoly, a market structure in which a small number of interdependent firms compete. In analyzing oligopoly, we cannot rely on the same types of graphs we use in analyzing perfect competition and monopolistic competition—for two reasons:

1. We need to use economic models that allow us to analyze the more complex business strategies of large oligopoly firms. These strategies involve more than choosing the profit-maximizing price and output.
2. Even in determining the profit-maximizing price and output for an oligopoly firm, demand curves and cost curves are not as useful as in the cases of perfect competition and monopolistic competition. We are able to draw the demand curves for competitive firms by assuming that the prices these firms charge have no effect on the prices other firms in their industries charge. This assumption is realistic when each firm is small relative to the market. It is not a realistic assumption, however, for firms that are as large relative to their markets as Microsoft, General Motors, or Walmart.

When large firms cut their prices, their rivals in the industry often—but not always—respond by also cutting their prices. Because we don't know for sure how other firms will respond to a price change, we don't know the quantity an oligopolist will sell at a particular price. In other words, it is difficult to know what an oligopolist's demand curve will look like. As we have seen, a firm's marginal revenue curve depends on its demand curve. If we don't know what an oligopolist's demand curve looks like, we also don't know what its marginal revenue curve looks like. Because we don't know marginal revenue, we can't calculate the profit-maximizing level of output and the profit-maximizing price the way we do for competitive firms.

The approach we use in this chapter to analyze competition among oligopolists is called *game theory*. Game theory can be used to analyze any situation in which groups or individuals interact. In the context of economic analysis, game theory is the study of the decisions of firms in industries where the profit of each firm depends on its interactions with other firms. It has also been applied to strategies for nuclear war, international trade negotiations, and political campaigns, among many other examples.

14.1 Oligopoly and Barriers to Entry

LEARNING OBJECTIVE: Show how barriers to entry explain the existence of oligopolies.

Oligopoly A market structure in which a small number of interdependent firms compete.

An **oligopoly** is an industry with only a few firms. This market structure lies between competitive industries, which have many firms, and monopolies, which have only a single firm. One measure of the extent of competition in an industry is the *concentration ratio*. Every five years, the U.S. Bureau of the Census publishes four-firm concentration ratios that measure the fraction of each industry's sales accounted for by its four largest firms. Most economists believe that a four-firm concentration ratio greater than 40 percent indicates that an industry is an oligopoly.

However, concentration ratios have the following flaws as measures of the extent of competition in an industry:

1. They do not include the goods and services that foreign firms export to the United States.

Retail Trade		Manufacturing	
Industry	Four-Firm Concentration Ratio	Industry	Four-Firm Concentration Ratio
Discount department stores (Walmart and Target)	97%	Cigarettes (Phillip Morris and R.J. Reynolds)	98%
Warehouse clubs and supercenters (Sam's Club and BJ's Wholesale Club)	94%	Beer (Anheuser-Busch and MillerCoors)	90%
College bookstores (Barnes & Noble and Follett)	75%	Computers (Hewlett-Packard and Dell)	87%
Hobby, toy, and game stores (Toys "R" Us and Michael's)	72%	Aircraft (Boeing and Lockheed Martin)	81%
Radio, television, and other electronic stores (Best Buy and Apple)	70%	Breakfast cereal (Kellogg's and General Mills)	80%
Athletic footwear stores (Footlocker and Champs)	68%	Dog and cat food (Mars and Procter & Gamble)	71%
Pharmacies and drugstores (Walgreens and CVS Caremark)	63%	Automobiles (General Motors and Ford)	68%

Table 14.1
Examples of Oligopolies in Retail Trade and Manufacturing

- They are calculated for the national market, even though the competition in some industries, such as restaurants or college bookstores, is mainly local.
- They do not account for competition that sometimes exists between firms in different industries. For example, Walmart is included in the discount department store industry but also competes with firms in the supermarket industry and the retail toy store industry.

Some economists prefer another measure of competition, known as the *Herfindahl-Hirschman Index* (see Chapter 15). Despite their shortcomings, concentration ratios can provide a general idea of the extent of competition in an industry.

Table 14.1 lists examples of oligopolies in manufacturing and retail trade (along with representative firms from each industry). The Bureau of the Census does not track the streaming music industry separately, but in 2015, just a few firms—including Apple, Spotify, Google, and Rdio—accounted for more than 90 percent of paid music streaming subscriptions, making the industry an oligopoly.

Barriers to Entry

Why do oligopolies exist? Why aren't there many more firms in the computer, discount department store, beer, or video game console industries? Recall that new firms will enter industries when existing firms are earning an economic profit. But new firms often have difficulty entering an oligopoly. Anything that keeps new firms from entering an industry in which firms are earning an economic profit is called a **barrier to entry**. Three important barriers to entry are economies of scale, ownership of a key input, and government-imposed barriers.

Economies of Scale The most important barrier to entry is **economies of scale**, which exist when a firm's long-run average costs fall as the firm increases output (see Chapter 11). The greater the economies of scale, the smaller the number of firms that will be in the industry. Figure 14.1 illustrates this point.

Barrier to entry Anything that keeps new firms from entering an industry in which firms are earning economic profits.

Economies of scale The situation when a firm's long-run average costs fall as the firm increases output.

MyEconLab Animation

Figure 14.1

Economies of Scale Help Determine the Extent of Competition in an Industry

An industry will be competitive if the minimum point on the typical firm's long-run average cost curve ($LRAC_1$) occurs at a level of output that is a small fraction of total industry sales, such as Q_1 . The industry will be an oligopoly if the minimum point comes at a level of output that is a large fraction of industry sales, such as Q_2 .

If economies of scale are relatively unimportant in the industry, the typical firm's long-run average cost curve ($LRAC$) will reach a minimum at a level of output (Q_1 in Figure 14.1) that is a small fraction of total industry sales. The industry will have room for a large number of firms and will be competitive. If economies of scale are significant, the typical firm will not reach the minimum point on its long-run average cost curve (Q_2 in Figure 14.1) until it has produced a large fraction of industry sales. In that case, the industry will have room for only a few firms and will be an oligopoly.

Economies of scale can explain why there is much more competition in the restaurant industry than in the music streaming industry. Because very large restaurants do not have significantly lower average costs than smaller restaurants, the restaurant industry has room for many firms. In contrast, a large music streaming firm such as Spotify has much lower average costs than would a small music streaming firm, partly because a large firm can spread the high fixed costs of streaming music—including very large server capacity, large research and development costs for its app, and the costs of the complex accounting necessary to keep track of the payments to the musicians and other copyright holders whose songs are being streamed—over a much larger quantity of subscriptions sold.

Ownership of a Key Input If production of a good requires a particular input, then control of that input can be a barrier to entry. For many years, the Aluminum Company of America (Alcoa) controlled most of the world's supply of high-quality bauxite, the mineral needed to produce aluminum. The only way other companies could enter the industry to compete with Alcoa was to recycle aluminum. The De Beers Company of South Africa was able to block competition in the diamond market by controlling the output of most of the world's diamond mines. Until the 1990s, Ocean Spray had very little competition in the market for fresh and frozen cranberries because it controlled almost the entire supply of cranberries. Even today, Ocean Spray controls about 65 percent of the cranberry crop through agreements with 650 cranberry growers.

Government-Imposed Barriers Firms sometimes try to convince the government to impose barriers to entry. Many large firms employ *lobbyists* to persuade state legislators and members of Congress to pass laws that are favorable to the economic interests of the firms. There are tens of thousands of lobbyists in Washington,

DC, alone. Top lobbyists command annual salaries of \$300,000 or more, which indicates the value firms place on their activities. Three important government-imposed barriers to entry are patents, licensing requirements, and restrictions on international trade.

A **patent** gives a firm the exclusive right to a new product for a period of 20 years from the date the patent application is filed with the government. Governments use patents to encourage firms to carry out research and development of new and better products and better ways of producing existing products. Output and living standards increase faster when firms devote resources to research and development, but a firm that spends money to develop a new product may not earn much profit if other firms can copy the product. For example, the pharmaceutical company Merck spends more than \$5 billion per year on developing new prescription drugs. If rival companies could freely produce these new drugs as soon as Merck developed them, most of the firm's investment would be wasted. Because Merck can patent a new drug, the firm can charge higher prices during the years the patent is in force and make an economic profit on its successful innovation.

Governments also restrict competition through *occupational licensing*. For example, doctors and dentists in every state need licenses to practice. Licensing has expanded in recent years, though, to include occupations such as teeth whitening, irrigation contracting, and art therapy. Nearly one-third of professions in the United States currently require a license. The justification for the laws is to protect the public from incompetent practitioners, but by restricting the number of people who can enter the licensed professions, the laws also raise prices. Studies have shown that states that make it harder to earn a dentist's license have prices for dental services that are about 15 percent higher than in other states. Similarly, states that require a license for out-of-state firms to sell contact lenses have higher prices for contact lenses. When state licenses are required for occupations such as hair braiding or yoga instruction, restricting competition is the main result.

Governments also impose barriers to entering some industries by imposing tariffs and quotas on foreign competition. A *tariff* is a tax on imports, and a *quota* limits the quantity of a good that can be imported into a country (see Chapter 9). A quota on foreign sugar imports severely limits competition in the U.S. sugar market. As a result, U.S. sugar companies can charge prices that are much higher than the prices companies outside the United States charge.

Patent The exclusive right to a product for a period of 20 years from the date the patent application is filed with the government.

Hard Times in Atlantic City

In the early twentieth century, Atlantic City, New Jersey, was a booming resort town and vacation destination with many hotels being

built along the city's famed boardwalk. (The properties in the Monopoly board game are named after streets in Atlantic City.) By the 1950s, Atlantic City was in economic decline because low-priced airline travel made it possible for people in northeastern states to travel to vacation destinations such as Miami and the Caribbean. At that time, casino gambling was illegal in the United States everywhere outside of Nevada.

In an attempt to attract visitors back to Atlantic City, in 1976 New Jersey voters passed a referendum to legalize gambling. Several gambling casinos opened in Atlantic City beginning in 1978 and were initially very profitable, attracting people from the Mid-Atlantic and Northeastern states. Entrepreneurs in these states were unable to compete with the Atlantic City casinos because casino gambling was illegal in their states. In effect, the government had imposed legal barriers to entry into the casino gambling industry.

Eventually, though, some other eastern states repealed their laws against casino gambling, and entrepreneurs opened new casinos in those states. By 2014, casino

New competition from nearby states that established casinos contributed to Atlantic City closing 4 of its 12 casinos, including the Trump Plaza.

gambling was legal in Pennsylvania, New York, Connecticut, Delaware, and Maryland. The entry of these new casinos caused a sharp decline in the demand for Atlantic City casinos. In particular, gamblers in the large New York City market now had several casinos that were closer than those in Atlantic City. By 2014, the revenues of Atlantic City casinos, which had peaked at \$5.2 billion in 2006, had fallen to \$2.5 billion.

In 2014, 4 of the city's 12 gambling casinos announced that they would be closing. Most shockingly, 1 of the 4 was the Revel Casino Hotel, which had opened only two years before, at a cost of \$2.4 billion. Several other casinos were also in danger of failing.

The casino industry in Atlantic City prospered when government regulations limited the competition they faced. As governments began to remove these legal barriers to entry, the profitability of the casinos sharply declined.

In summary, to earn an economic profit, all firms would like to charge a price well above average cost, but earning an economic profit attracts new firms to enter the industry. Eventually, the increased competition forces price down to average total cost, and firms just break even. In an oligopoly, barriers to entry prevent—or at least slow down—entry, which allows firms to earn an economic profit over a longer period.

14.2 Game Theory and Oligopoly

LEARNING OBJECTIVE: Use game theory to analyze the strategies of oligopolistic firms.

Game theory The study of how people make decisions in situations in which attaining their goals depends on their interactions with others; in economics, the study of the decisions of firms in industries where the profits of a firm depend on its interactions with other firms.

As we noted at the beginning of the chapter, economists analyze oligopolies by using *game theory*, which was developed during the 1940s by the mathematician John von Neumann and the economist Oskar Morgenstern. **Game theory** is the study of how people make decisions in situations in which attaining their goals depends on their interactions with others. In oligopolies, the interactions among firms are crucial in determining profitability because the firms are large relative to the market.

In all games—whether poker, chess, or Monopoly—the interactions among the players are crucial in determining the outcome. In addition, games share three key characteristics:

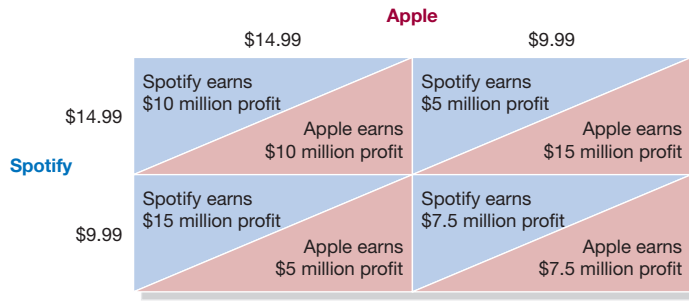

1. **Rules** that determine what actions are allowable
2. **Strategies** that players employ to attain their objectives in the game
3. **Payoffs** that are the results of the interactions among the players' strategies

In business situations, the rules of the "game" include not just laws that a firm must obey but also other factors beyond a firm's control—at least in the short run—such as its production function. A **business strategy** is a set of actions that a firm takes to achieve a goal, such as maximizing profit. The *payoff* is the profit a firm earns as a result of how its strategies interact with the strategies of other firms. The best way to understand the game theory approach is to look at an example.

Business strategy Actions that a firm takes to achieve a goal, such as maximizing profits.

A Duopoly Game: Price Competition between Two Firms

In this simple example, we use game theory to analyze price competition in a *duopoly*—an oligopoly with two firms. We assume that Apple and Spotify are the only two firms selling subscriptions for music streaming. In 2015, both firms were charging \$9.99 per month in exchange for allowing consumers to choose from 30 million songs

MyEconLab Animation

Figure 14.2

A Duopoly Game

Spotify’s profit is shown in blue, and Apple’s profit is shown in red. Spotify and Apple would each make a profit of \$10 million per month on sales of streaming music subscriptions if they both charge \$14.99. However, each firm has an incentive to undercut the other by charging a lower price. If both firms charge \$9.99, they would each make a profit of only \$7.5 million per month.

available for streaming. Some industry analysts thought that the services might have difficulty becoming consistently profitable unless the companies charged a monthly price of \$14.99. Let’s focus on the pricing decisions Apple and Spotify face. We assume that the managers of the two firms have to decide whether to charge \$9.99 or \$14.99 for subscriptions. Which price will be more profitable depends on the price the other firm charges. Choosing a price is an example of a business strategy. In Figure 14.2, we organize the possible outcomes that result from the actions of the two firms into a **payoff matrix**, which is a table that shows the payoffs that each firm earns from every combination of strategies by the firms.

Apple’s profit is shown in red, and Spotify’s profit is shown in blue. Each of the four quadrants of the payoff matrix shows the results of different combinations of strategies the two firms use. For example, if Apple and Spotify both charge \$14.99 per month for unlimited music streaming, we are in the upper-left quadrant, which shows that each firm will make a profit of \$10 million per month. If Apple charges the lower price of \$9.99 while Spotify charges \$14.99, Apple will gain many of Spotify’s customers. Apple’s profit will be \$15 million, and Spotify’s profit will be only \$5 million. Similarly, if Spotify charges \$9.99 while Apple charges \$14.99, Apple’s profit will be only \$5 million while Spotify’s profit will be \$15 million. If both firms charge \$9.99, each will earn a profit of \$7.5 million per month.

Clearly, the firms will be better off if they both charge \$14.99 per month. But will they both charge this price? One possibility is that Apple’s managers and Spotify’s managers will get together and *collude* by agreeing to charge the higher price. **Collusion** is an agreement among firms to charge the same price or otherwise not to compete. Unfortunately for Apple and Spotify—but fortunately for their customers—collusion is against the law in the United States and Europe. The government can fine companies that collude and send the managers involved to prison.

Apple’s managers can’t legally discuss their pricing decision with Spotify’s managers, so they have to predict what the other managers will do. Suppose Apple’s managers are convinced that Spotify’s managers will charge \$14.99. In this case, Apple’s managers will definitely charge \$9.99 because doing so will increase Apple’s profit from \$10 million to \$15 million. But suppose that, instead, Apple’s managers are convinced that Spotify’s managers will charge \$9.99. Then Apple’s managers also will definitely charge \$9.99 because that will increase their profit from \$5 million to \$7.5 million. In fact, regardless of which price Spotify’s managers decide to charge, Apple’s managers are better off charging \$9.99. So, we know that Apple’s managers will choose a price of \$9.99 per month.

Now consider the situation from the point of view of Spotify’s managers. They are in the same position as Apple’s managers, so we can expect them to make the same decision to charge \$9.99 per month. In this situation, both firms have a *dominant strategy*. A **dominant strategy** is the best strategy for a firm, no matter what strategies other firms use. The result is an equilibrium where both firms charge \$9.99 per month. This situation is an equilibrium because each firm is maximizing profit, *given the price chosen by the other firm*. In other words, neither firm can increase its profit by changing its price, given the price chosen by the other firm. An equilibrium in which each firm chooses the best strategy, given the strategies chosen by other firms, is called a **Nash equilibrium**, named after the late Nobel Laureate John Nash of Princeton University, a pioneer in the development of game theory.

Payoff matrix A table that shows the payoffs that each firm earns from every combination of strategies by the firms.

Collusion An agreement among firms to charge the same price or otherwise not to compete.

Dominant strategy A strategy that is the best for a firm, no matter what strategies other firms use.

Nash equilibrium A situation in which each firm chooses the best strategy, given the strategies chosen by other firms.

Cooperative equilibrium An equilibrium in a game in which players cooperate to increase their mutual payoff.

Noncooperative equilibrium An equilibrium in a game in which players do not cooperate but pursue their own self-interest.

Prisoner's dilemma A game in which pursuing dominant strategies results in noncooperation that leaves everyone worse off.

Firm Behavior and the Prisoner's Dilemma

Notice that the equilibrium in Figure 14.2 is not very satisfactory for either firm. The firms earn \$7.5 million in profit each month by charging \$9.99, but they could have earned \$10 million in profit if they both had charged \$14.99. By “cooperating” and charging the higher price, they would have achieved a *cooperative equilibrium*. In a **cooperative equilibrium**, players cooperate to increase their mutual payoff. We have seen, though, that the outcome of this game is likely to be a **noncooperative equilibrium**, in which each firm pursues its own self-interest.

A situation like the one in Figure 14.2, in which pursuing dominant strategies results in noncooperation that leaves everyone worse off, is called a **prisoner's dilemma**. The game gets its name from the problem two suspects face when arrested for a crime. If the police lack other evidence, they may separate the suspects and offer each a reduced prison sentence in exchange for confessing to the crime and testifying against the other suspect. Because each suspect has a dominant strategy to confess to the crime, they both will confess and serve a jail term, even though they would have gone free if they both had remained silent.

Don't Let This Happen to You

Don't Misunderstand Why Each Firm Ends Up Charging a Price of \$9.99

It is tempting to think that Apple and Spotify would each charge \$9.99 rather than \$14.99 for a month of unlimited music streaming because each is afraid that the other firm will charge \$9.99. In fact, fear of being undercut by the other firm charging a lower price is not the key to understanding each firm's pricing strategy. Notice that charging \$9.99 is the most profitable strategy for each firm, regardless of which price the other firm decides to charge. For

example, even if Apple's managers somehow knew for sure that Spotify's managers intended to charge \$14.99, Apple would still charge \$9.99 because its profits would be \$15 million instead of \$10 million. Spotify's managers are in the same situation. That is why charging \$9.99 is a dominant strategy for both firms.

Solved Problem 14.2

Is Same-Day Delivery a Prisoner's Dilemma for Walmart and Amazon?

Online shopping has increased dramatically in the past 15 years. One drawback consumers face when shopping online, though, is the wait to receive a good compared with going to a store and buying it off the shelf. Amazon has been a pioneer in reducing delivery times, including offering a same-day delivery service in several cities. To avoid losing customers to Amazon, several other firms, including Walmart, eBay, and Google, have begun offering same-day delivery in some cities. Firms typically hire people to go to retail stores, buy the products customers have ordered, and deliver the products directly to them. Some retail analysts agree that this process is so costly that the firms are actually losing money on most same-day delivery orders. Failing to offer the service, though, might cause customers to take all of their business—including their profitable orders—to firms that did offer the service.

Suppose Amazon and Walmart are competing with same-day delivery in a particular city. Construct a payoff matrix using the following hypothetical information:

- If neither firm offers same-day delivery, Amazon and Walmart each earn a profit of \$7 million per month.
- If both firms offer same-day delivery, Amazon and Walmart each earn a profit of \$5 million per month.
- If Amazon offers same-day delivery and Walmart doesn't, Amazon earns a profit of \$9 million, and Walmart earns a profit of \$4 million.
- If Walmart offers same-day delivery and Amazon doesn't, Walmart earns a profit of \$9 million, and Amazon earns a profit of \$4 million.

- a. If Amazon wants to maximize profit, will it offer same-day delivery? Briefly explain.
- b. If Walmart wants to maximize profit, will it offer same-day delivery? Briefly explain.
- c. Is there a Nash equilibrium to this game? If so, what is it?

Solving the Problem

Step 1: Review the chapter material. This problem uses payoff matrixes to analyze a business situation, so you may want to review the section “A Duopoly Game: Price Competition between Two Firms,” which begins on page 534.

Step 2: Construct the payoff matrix.

		Walmart	
		Don't Offer	Offer
Amazon	Don't Offer	Amazon earns \$7 million profit Walmart earns \$7 million profit	Amazon earns \$4 million profit Walmart earns \$9 million profit
	Offer	Amazon earns \$9 million profit Walmart earns \$4 million profit	Amazon earns \$5 million profit Walmart earns \$5 million profit

Step 3: Answer part (a) by showing that Amazon has a dominant strategy of offering same-day delivery. If Walmart doesn't offer the service, Amazon will make \$9 million if it offers the service but only \$7 million if it doesn't. If Walmart offers the service, Amazon will make \$5 million if it offers the service but only \$4 million if it doesn't. Therefore, offering the service is a dominant strategy for Amazon.

Step 4: Answer part (b) by showing that Walmart has a dominant strategy of offering same-day delivery. Walmart is in the same position as Amazon, so it also has a dominant strategy of offering the service.

Step 5: Answer part (c) by showing that there is a Nash equilibrium for this game. Both firms offering same-day delivery is a Nash equilibrium. Given that Amazon is offering the service, Walmart's best strategy is to offer the service. Given that Walmart is offering the service, Amazon's best strategy is to offer it. Therefore, offering same-day delivery is the optimal decision for both firms, given the decision by the other firm.

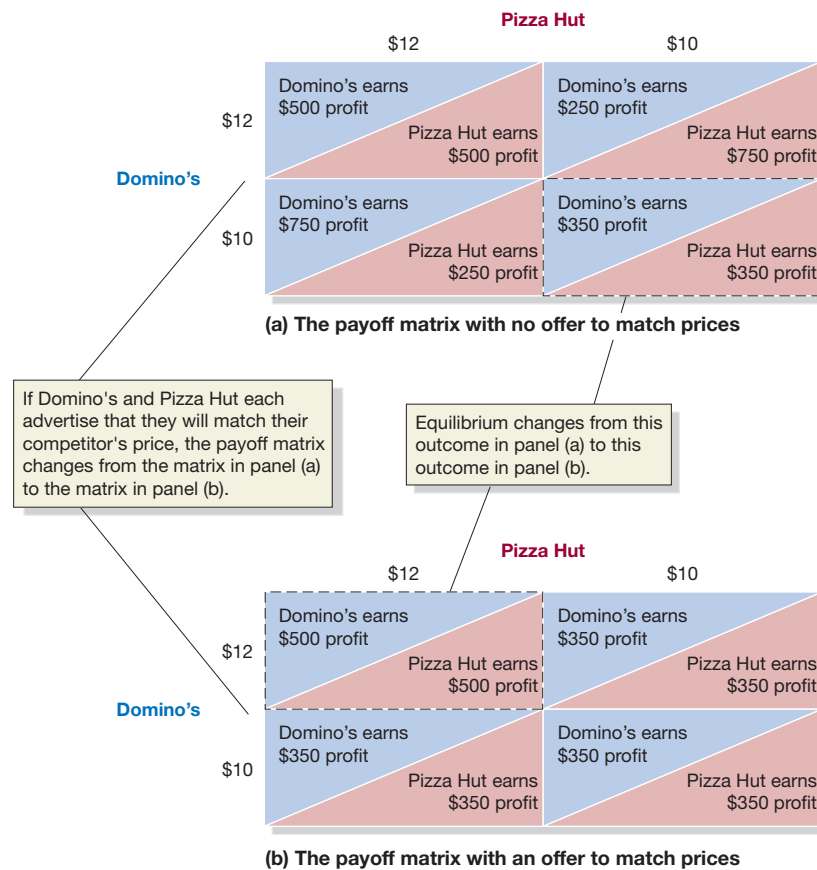

Extra Credit: This game is another example of the prisoner's dilemma. Amazon and Walmart would be more profitable if neither offered same-day delivery, thereby saving the high cost of hiring people to deliver individual packages in a short amount of time. Each firm's dominant strategy is to offer the service, however, so they end up in an equilibrium where both offer the service, and their profits are reduced.

Your Turn: For more practice, do related problems 2.10 and 2.11 on page 552 at the end of this chapter.

Can Firms Escape the Prisoner's Dilemma?

Although the prisoner's dilemma game seems to show that cooperative behavior always breaks down, we know that people often cooperate to achieve their goals, and firms find ways to cooperate by not competing on price. The reason the basic prisoner's dilemma story is not always applicable in the real world is that it assumes the game will be played *only once*. Most business situations, however, are repeated over and over. For example, consider the following situation: Suppose that in a small town, the

MyEconLab Animation

Figure 14.3 Changing the Payoff Matrix in a Repeated Game

Domino's and Pizza Hut can change the payoff matrix for selling pepperoni pizzas by advertising that each will match its competitor's price. This retaliation strategy provides a signal that one restaurant charging a lower price will be met automatically by the other restaurant charging a lower price. In the payoff matrix in panel (a), there is no advertisement about matching prices, and each restaurant benefits if it charges \$10 when the other

charges \$12. In the payoff matrix in panel (b), after advertising that they will match prices, the managers have only two choices: They can charge \$12 and receive a profit of \$500 per day, or they can charge \$10 and receive a profit of \$350 per day. The equilibrium shifts from the prisoner's dilemma result of both restaurants charging the low price and receiving low profits to both restaurants charging the high price and receiving high profits.

only places to buy a pizza are Domino's and Pizza Hut. Assume that the managers will charge either \$12 or \$10 for a large pepperoni pizza. Panel (a) of Figure 14.3 gives the payoff matrix. Notice that each manager has an incentive to charge the lower price. Once again, the firms appear to be caught in a prisoner's dilemma. But the managers will not play this game only once; each day they will decide again what price to charge for a pizza. In the language of game theory, the managers are playing a *repeated game*, where the losses from not cooperating are greater than in a game played only once, and players can employ *retaliation strategies* against other players who don't cooperate. As a result, firms have a greater incentive to cooperate.

Panel (a) of Figure 14.3 shows that Domino's and Pizza Hut are earning \$150 less per day by both charging \$10 instead of \$12 for the pizza. Every day that passes with both stores charging \$10 increases the total amount lost: A year of charging \$10 will cause each store to lose more than \$50,000 in profit. This lost profit increases the incentive for the store managers to cooperate by *implicitly* colluding. Remember that *explicit* collusion—such as the managers meeting and agreeing to charge \$12—is illegal. But if the managers can find a way to signal each other that they will charge \$12, they may be within the law.

Suppose that Domino's and Pizza Hut both advertise that they will match the lowest price offered by any competitor—in our simple example, they are each other's only competitor. These advertisements are signals to each other that they intend to charge \$12 for a pizza. The signal is clear because each restaurant knows that if it charges \$10, the other restaurant will automatically retaliate by also lowering its price to \$10. The offer to match prices is a good *enforcement mechanism* because it guarantees that if either restaurant fails to cooperate and charges the lower price, the competing restaurant will automatically punish that restaurant by also charging the lower price. As Figure 14.3 shows, the restaurants have changed the payoff matrix they face.

With the original payoff matrix in panel (a), there are no advertisements about matching prices, and each restaurant makes more profit if it charges \$10 when the other charges \$12. The advertisements about matching prices change the payoff matrix to the one shown in panel (b). Now the managers can charge \$12 and receive a profit of \$500 per day, or they can charge \$10 and receive a profit of \$350 per day. The equilibrium shifts from the prisoner's dilemma result of both managers charging the low price and receiving low profits to a result where both charge the high price and receive the high profits. An advertisement offering to match competitors' prices might seem to benefit consumers, but game theory shows that it actually may hurt consumers by helping to keep prices high.

One form of implicit collusion occurs as a result of **price leadership**, where one firm takes the lead in announcing a price change that other firms in the industry then match. For example, through the 1970s, General Motors (GM) would announce a price change in the fall at the beginning of a model year, and Ford and Chrysler would match GM's price change. In some cases, such as in the airline industry, firms have attempted to act as price leaders but failed when other firms in the industry have refused to cooperate.

MyEconLab Video

Do Airlines Collude on Capacity to Keep Prices High?

Coordinating prices is easier in some industries than in others.

Fixed costs in the airline industry are very large, and marginal costs are very small. The marginal cost of flying one more passenger from Chicago to New York is no more than a few dollars: the cost of another snack served and a little additional jet fuel. As a result, airlines often engage in last-minute price cutting to fill the remaining empty seats on a flight. Even a low-price ticket will increase marginal revenue more than marginal cost. As with other oligopolies, if all airlines cut prices, industry profits will decline. Airlines therefore continually adjust their prices while at the same time monitoring their rivals' prices and retaliating against them for either cutting prices or failing to go along with price increases.

In recent years, mergers in the airline industry have increased the possibility of implicit collusion. In 2015, just four airlines—American, Delta Airlines, United, and Southwest—flew 80 percent of all passengers. Smaller airlines, such as JetBlue, Spirit Airlines, and Allegiant Air, provided competition on some routes, but the four big airlines were the only ones offering service between many pairs of cities.

A 40 percent decline in jet fuel costs during 2014 saved the airlines billions of dollars and allowed them to earn record profits. During previous periods of high profits, the airlines had often invested in expanding their capacity by buying additional planes or flying more routes. Adding more capacity, though, means having more tickets to sell and increases the likelihood of price cutting to fill the seats. Investment analysts attempt

Airlines saved a lot of money due to low fuel costs in 2014, but they used very little of that savings to expand capacity.

to predict the future profitability of firms because the firms' stock prices depend on their profitability. Some analysts predicted that the airlines' future profitability would decline because the analysts expected the airlines to add capacity. As a result, the prices of the airlines' stocks fell. Top managers don't like to see declines in their firms' stock prices in part because their own compensation is often tied to the stock price and also because a lower stock price means the firm receives a smaller amount if it raises funds by selling stock. As a result, in an attempt to reassure analysts and stock investors that the airlines' profits would remain high, top managers of all four major airlines publicly stated that they intended to undertake only modest increases in capacity.

Were these executives just responding to the concerns of investment analysts, or were they engaging in implicit collusion? If the four major airlines all declined to increase capacity, then the quantity of tickets to be sold would not increase as much, and it would be easier for them to avoid cutting prices. As we will discuss in Chapter 15, the U.S. Department of Justice is responsible for enforcing the laws against collusion. In July 2015, the Department of Justice began investigating the airlines to see if the managers' statements about not expanding capacity amounted to illegal collusion. As one airline industry analyst put it, "If you're listening as a Justice Department attorney, you'd say, 'Wait a minute, these guys are all saying the same thing, and that can't just happen naturally, can it?'"

The airlines denied that they were colluding and argued that they were slowly expanding capacity not by adding new planes on new routes but by adding more seats to existing planes. One manager for Delta stated, "We're making the planes we have more efficient. Without building any infrastructure, we can transport more people." The Department of Justice's investigation would help determine whether the airlines were colluding ... and whether consumers could look forward to lower airline ticket prices in the future.

Cartels: The Case of OPEC

In the United States, firms cannot legally meet to agree on what prices to charge and how much to produce. But suppose they could. Would this be enough to guarantee that their collusion would be successful? The example of the Organization of the Petroleum Exporting Countries (OPEC) indicates that the answer to this question is "no." OPEC has 12 members, including Saudi Arabia, Kuwait, and other Arab countries, as well as Iran, Venezuela, and Nigeria. Together, these countries own more than 75 percent of the world's proven crude oil reserves, although they supply only about 35 percent of the total oil sold each year. OPEC operates as a **cartel**, which is a group of firms that collude by agreeing to restrict output to increase prices and profits. The members of OPEC meet periodically and agree on quotas, which are quantities of oil that each country agrees to produce. The quotas are intended to reduce oil production well below the competitive level to force up the price of oil and increase the profits of member countries.

Figure 14.4 shows oil prices from 1972 to mid-2015. The blue line shows the price of a barrel of oil in each year. Prices in general have risen since 1972, which has reduced the amount of goods and services that consumers can purchase with a dollar. The red line corrects for general price increases by measuring oil prices in terms of the dollar's purchasing power in 2015. The figure shows that OPEC succeeded in raising the price of oil during the mid-1970s and early 1980s, although political unrest in the Middle East and other factors also affected the price of oil during these years. Oil prices had been below \$3 per barrel in 1972 but rose to more

The blue line shows the price of a barrel of oil in each year. The red line measures the price of a barrel of oil in terms of the purchasing power of the dollar in 2015. By reducing oil production, OPEC was able to raise the world price of oil in the mid-1970s

and early 1980s. Sustaining high prices has been difficult over the long run, however, because OPEC members often exceed their output quotas.

than \$39 per barrel in 1980, which was more than \$115 measured in dollars of 2015 purchasing power. The figure also shows that OPEC has had difficulty sustaining the high prices of 1980 in later years, although oil prices rose sharply between 2004 and mid-2008, in part due to increasing demand from China and India. In the past few years, OPEC has also had difficulty maintaining oil prices because of a surge in U.S. production as oil companies have used “fracking” techniques to recover oil from shale deposits.

Game theory helps us understand why oil prices have fluctuated. If every member of OPEC cooperates and produces the low output level dictated by its quota, prices will be high, and the cartel will earn large profits. (Even though OPEC cannot raise prices as high as it did before U.S. production increased, it can still increase world oil prices if all of its members agree to restrict production.) Once the price has been driven up, however, each member has an incentive to stop cooperating and to earn even higher profits by increasing output beyond its quota. But if no country sticks to its quota, total oil output will increase, and profits will decline. In other words, OPEC is caught in a prisoner’s dilemma.

If the members of OPEC always exceeded their production quotas, the cartel would have no effect on world oil prices. In fact, the members of OPEC periodically meet and assign new quotas that, at least for a while, enable them to restrict output enough to raise prices. Two factors explain OPEC’s occasional success at behaving as a cartel. First, the members of OPEC are participating in a repeated game. As we have seen, being in a repeated game increases the likelihood of a cooperative outcome. Second, Saudi Arabia has far larger oil reserves than any other member of OPEC. Therefore, it has the most to gain from high oil prices and a greater incentive to cooperate. To see this, consider the payoff matrix shown in Figure 14.5. To keep things simple, let’s assume that OPEC has only two members: Saudi Arabia and Nigeria. In Figure 14.5, “Low Output” corresponds to cooperating with the OPEC-assigned output quota, and “High Output” corresponds to producing at maximum capacity. The payoff matrix shows the profits received per day by each country.

We can see that Saudi Arabia has a strong incentive to cooperate and maintain its low output quota. By keeping output low, Saudi Arabia can by itself significantly raise the world price of oil, increasing its own profits as well as those of other

MyEconLab Animation

Figure 14.5

The OPEC Cartel with Unequal Members

Because Saudi Arabia can produce much more oil than Nigeria, its output decisions have a larger effect on the price of oil. In the figure, Low Output corresponds to cooperating with the OPEC-assigned output quota, and High Output corresponds to producing at maximum capacity. Saudi Arabia has a dominant strategy to cooperate and produce a low output. Nigeria, however, has a dominant strategy not to cooperate and instead produce a high output. Therefore, the equilibrium of this game will occur with Saudi Arabia producing a low output and Nigeria producing a high output.

members of OPEC. Therefore, Saudi Arabia has a dominant strategy of cooperating with the quota and producing a low output. Nigeria, however, cannot by itself have much effect on the price of oil. Therefore, Nigeria has a dominant strategy of not cooperating and instead producing a high output. The equilibrium of this game will occur with Saudi Arabia producing a low output and Nigeria producing a high output. In fact, OPEC often operates in just this way. Saudi Arabia will cooperate with the quota, while the other 11 members produce at capacity. Because this is a repeated game, however, Saudi Arabia will occasionally produce more oil than its quota to intentionally drive down the price and retaliate against the other members for not cooperating.

14.3 Sequential Games and Business Strategy

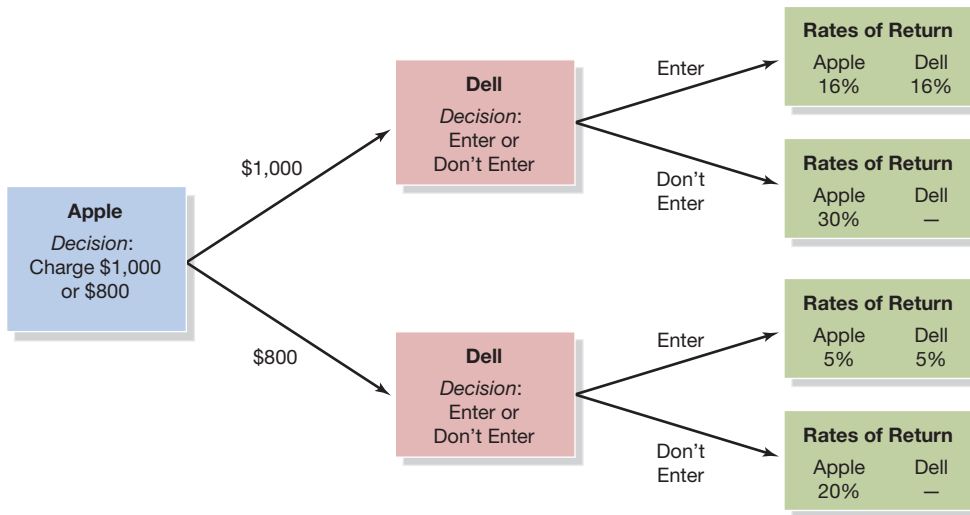

LEARNING OBJECTIVE: Use sequential games to analyze business strategies.

We have been analyzing games in which both players move simultaneously. In many business situations, however, one firm will act first, and then other firms will respond. These situations can be analyzed using *sequential games*. We will use sequential games to analyze two business strategies: deterring entry and bargaining between firms. To keep things simple, we consider situations that involve only two firms.

Deterring Entry

In Section 14.1, we saw that barriers to entry are a key to firms continuing to earn an economic profit. Can firms create barriers to deter new firms from entering an industry? Some recent research in game theory has focused on this question. Suppose that Apple and Dell are the only makers of very thin, light laptop computers. One factor firms consider in pricing a new product is the effect different prices have on the likelihood that competitors will enter the market. A high price might lead to a large profit if other firms do not enter the market, but if a high price attracts entry from other firms, it might actually result in a smaller profit. A low price, by deterring entry, might lead to a larger profit. Assume that managers at Apple have developed a very thin, light laptop before Dell has and are considering what price to charge. To break even by covering the opportunity cost of the funds used, laptops must provide a minimum rate of return of 15 percent on Apple's investment. If Apple has the market for this type of laptop to itself and charges a price of \$800, it will earn an economic profit by receiving a return of 20 percent. If Apple charges a price of \$1,000 and has the market to itself, it will receive a higher return of 30 percent.

It seems clear that Apple should charge \$1,000 for its laptops, but the managers are worried that Dell might also begin selling this type of laptop. If Apple charges \$800 and Dell enters the market, Apple and Dell will divide up the market, and both will earn only 5 percent on their investments, which is below the 15 percent return each firm needs to break even. If Apple charges \$1,000 and Dell enters, although the market will still be divided, the higher price means that each firm will earn 16 percent on its investment.

MyEconLab Animation

Figure 14.6 The Decision Tree for an Entry Game

Apple earns its highest return if it charges \$1,000 for its very thin, light laptop and Dell does not enter the market. But at that price, Dell will enter the market, and Apple will earn only 16 percent. If Apple charges \$800, Dell will not enter because Dell will suffer an economic loss by receiving only a 5 percent return on

its investment. Therefore, Apple's best decision is to deter Dell's entry by charging \$800. Apple will earn an economic profit by receiving a 20 percent return on its investment. Note that the dashes (—) indicate the situation where Dell does not enter the market and so makes no investment and receives no return.

Apple and Dell are playing a sequential game because Apple makes the first move—deciding what price to charge—and Dell responds. We can analyze a sequential game by using a *decision tree*, like the one shown in Figure 14.6. The boxes in the figure represent *decision nodes*, which are points where the firms must make the decisions contained in the boxes. At the left, Apple makes the initial decision of what price to charge, and then Dell responds by either entering the market or not. The decisions made are shown beside the arrows. The *terminal nodes*, in green at the right side of the figure, show the resulting rates of return.

Let's start with Apple's initial decision. If Apple charges \$1,000, then the arrow directs us to the upper red decision node for Dell. If Dell decides to enter, it will earn a 16 percent rate of return on its investment, which represents an economic profit because it is above the opportunity cost of the funds involved. If Dell doesn't enter, Apple will earn 30 percent, and Dell will not earn anything in this market (indicated by the dash). Apple's managers can conclude that if they charge \$1,000 for their laptops, Dell will enter the very thin, light laptop market, and both firms will earn 16 percent on their investments.

If Apple decides to charge \$800, then the arrow directs us to the lower red decision node for Dell. If Dell decides to enter, it will earn only a 5 percent rate of return. If it doesn't enter, Apple will earn 20 percent, and Dell will not earn anything in this market. Apple's managers can conclude that if they charge \$800, Dell will not enter, and Apple will earn 20 percent on its investment.

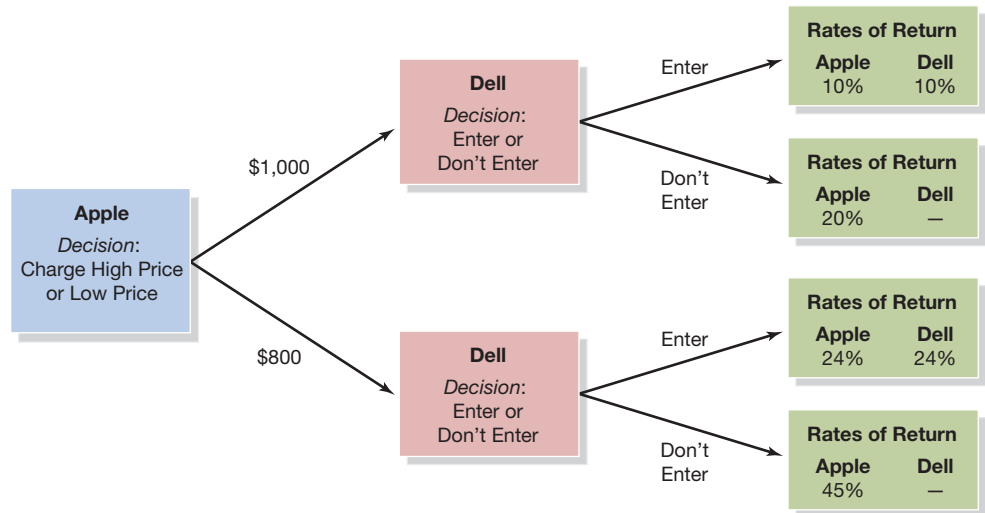

This analysis should lead Apple's managers to conclude that they can charge \$1,000 and earn 16 percent—because Dell will enter—or they can charge \$800 and earn 20 percent by deterring Dell's entry. Using a decision tree helps Apple's managers make the correct choice and charge \$800 to deter Dell's entry into this market. Note that our discussion is simplified because we are ignoring other characteristics, apart from price, on which the firms also compete. In practice, Apple charged a relatively high price for its lightweight laptop, the MacBook Air, which caused Dell to enter the market with the lower-priced XPS 15z Ultrabook. Apple's managers believed that the MacBook Air's features would remain attractive to consumers, despite the XPS 15z Ultrabook having a lower price. Time will tell whether Apple made the correct decision by not charging a low enough price to deter Dell's entry.

Solved Problem 14.3

Is Deterring Entry Always a Good Idea?

Like any other business strategy, deterring entry is a good idea only if it has a higher payoff than alternative strategies. Use the following decision tree to decide whether Apple

should deter Dell from entering the market for very thin, light laptops. Assume that each firm must earn a 15 percent return on its investment to break even.

Solving the Problem

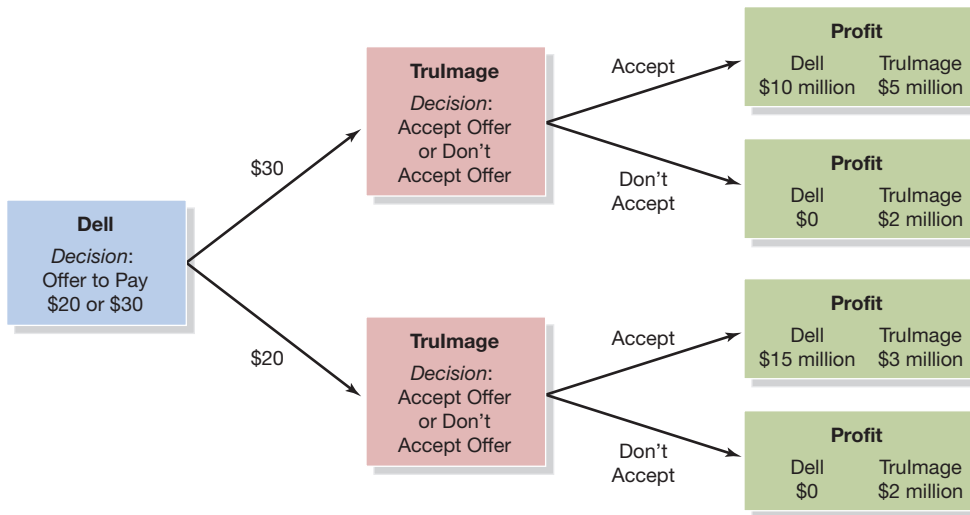

- Step 1: Review the chapter material.** This problem is about sequential games, so you may want to review the section “Deterring Entry,” which begins on page 542.
- Step 2: Determine how Dell will respond to Apple’s decision.** If Apple charges \$1,000 for its very thin, light laptops, Dell will not enter the market because the return on its investment represents an economic loss. If Apple charges \$800, Dell will enter because it will earn a return that represents an economic profit.
- Step 3: Given how Dell will react, determine which strategy maximizes profits for Apple.** If Apple charges \$1,000, it will deter Dell’s entry, and the rate of return on its investment will be 20 percent. If Apple charges \$800, Dell will enter, but because these low prices will substantially increase the market for these laptops, Apple will actually earn a higher return of 24 percent. By splitting the market with Dell at a lower price, Apple earns a higher return than it would have if it had the whole market to itself at a high price.
- Step 4: State your conclusion.** Like any other business strategy, deterrence is worth pursuing only if the payoff is higher than for other strategies. In this case, expanding the market for very thin, light laptops by charging a lower price has a higher payoff for Apple, even given that Dell will enter the market.

Bargaining

The success of many firms depends on how well they bargain with other firms. For example, firms often must bargain with their suppliers over the prices they pay for inputs. Suppose that TruImage is a small firm that has developed software that

MyEconLab Animation

Figure 14.7 The Decision Tree for a Bargaining Game

Dell earns the highest profit if it offers a contract price of \$20 per copy and Trulmage accepts the contract. Trulmage earns the highest profit if Dell offers it a contract of \$30 per copy and it accepts the contract. Trulmage may attempt to bargain by

threatening to reject a \$20-per-copy contract. But Dell knows this threat is not credible because once Dell has offered a \$20-per-copy contract, Trulmage's profits are higher if it accepts the contract than if it rejects it.

improves how pictures from digital cameras or smartphones are displayed on computer screens. Trulmage currently sells its software only on its Web site and earns a profit of \$2 million per year. Dell informs Trulmage that it is considering installing the software on every new computer Dell sells. Dell expects to sell more computers at a higher price if it can install Trulmage's software on its computers. The two firms begin bargaining over what price Dell will pay Trulmage for its software.

The decision tree in Figure 14.7 illustrates this bargaining game. At the left, Dell makes the initial decision about what price to offer Trulmage for its software, and then Trulmage responds by either accepting or rejecting the contract offer. Suppose that Dell offers Trulmage a contract price of \$30 per copy for its software. If Trulmage accepts this contract, its profit will be \$5 million per year, and Dell will earn \$10 million in additional profit. If Trulmage rejects the contract, its profit will be the \$2 million per year it earns selling its software on its Web site, and Dell will earn zero additional profit.

Now, suppose Dell offers Trulmage a contract price of \$20 per copy. If Trulmage accepts this contract, its profit will be \$3 million per year, and Dell will earn \$15 million in additional profit. If Trulmage rejects this contract, its profit will be the \$2 million it earns selling its software on its Web site, and Dell will earn zero additional profit. Clearly, for Dell, a contract price of \$20 per copy is more profitable, while for Trulmage, a contract price of \$30 per copy is more profitable.

Suppose Trulmage attempts to obtain a favorable outcome from the bargaining by telling Dell that it will reject a \$20-per-copy contract price. If Dell believes this threat, then it will offer Trulmage a \$30-per-copy contract price because Dell is better off with the \$10 million additional profit that will result from Trulmage accepting the contract than with the zero additional profit Dell will earn if Trulmage rejects the \$20-per-copy contract price. This result is a Nash equilibrium because neither firm can increase its profit by changing its choice—*provided that Dell believes Trulmage's threat*. But is Trulmage's threat credible? Once Dell has offered Trulmage the \$20 contract price, Trulmage's choices are to accept the contract and earn \$3 million or reject the contract and earn only \$2 million. Because rejecting the contract reduces Trulmage's profit, Trulmage's threat to reject the contract is not credible, and Dell should ignore it.

As a result, we would expect Dell to use the strategy of offering Trulmage a \$20-per-copy contract price and Trulmage to use the strategy of accepting the contract. Dell will earn an additional profit of \$15 million per year, and Trulmage will earn a profit of \$3 million per year. This outcome is called a *subgame-perfect equilibrium*. A subgame-perfect equilibrium is a Nash equilibrium in which no player can make himself or herself better off by changing his or her decision at any decision node. In our simple bargaining game, each player has only one decision to make. As we have seen, Dell's profits are highest if it offers the \$20-per-copy contract price, and Trulmage's profits are highest if it accepts the contract. Typically, in sequential games of this type, there is only one subgame-perfect equilibrium.

Managers use decision trees like those in Figures 14.6 and 14.7 in business planning because they provide a systematic way of thinking through the implications of a strategy and of predicting the reactions of rivals. We can see the benefits of decision trees in the simple examples considered here. In the first example, Apple's managers can conclude that charging a low price is more profitable than charging a high price. In the second example, Dell's managers can conclude that Trulmage's threat to reject a \$20-per-copy contract is not credible.

14.4 The Five Competitive Forces Model

LEARNING OBJECTIVE: Use the five competitive forces model to analyze competition in an industry.

We have seen that the number of competitors in an industry affects a firm's ability to charge a price above average cost and earn an economic profit. The number of firms is not the only determinant of the level of competition in an industry, however. Michael Porter of the Harvard Business School has developed a model that shows how five competitive forces determine the overall level of competition in an industry.

In this section, we briefly discuss each of the five competitive forces: (1) competition from existing firms, (2) the threat from potential entrants, (3) competition from substitute goods or services, (4) the bargaining power of buyers, and (5) the bargaining power of suppliers.

Competition from Existing Firms

We have already seen that competition among firms in an industry can lower prices and profits. Consider another example: Educational Testing Service (ETS) produces the Scholastic Aptitude Test (SAT) and the Graduate Record Exam (GRE). High school students applying to college take the SAT, and college students applying to graduate school take the GRE. In 2015, ETS charged a price of \$52.50 to take the SAT, and it charged \$195 to take the GRE. Part of the explanation for this large price difference is that ETS faces competition in the market for tests given to high school students applying to college, where the SAT competes with the ACT Assessment, produced by ACT, Inc. But there is no competition for the GRE. As we saw in Section 14.2, when there are only a few firms in a market, it is easier for them to implicitly collude and to charge a price close to the monopoly price. In this case, however, competition from a single firm was enough to cause ETS to keep the price of the SAT near the competitive level.

Competition in the form of advertising, better customer service, or longer warranties can also reduce profits by raising costs. For example, online booksellers Amazon.com and BarnesandNoble.com have competed by offering low-cost—or free—shipping, by increasing their customer service staffs, and by building more warehouses to provide faster deliveries. These activities have raised the booksellers' costs and reduced their profits.

MyEconLab Concept Check

The Threat from Potential Entrants

Firms face competition from companies that currently are not in the market but might enter. We have already seen how actions taken to deter entry can reduce profits. In our hypothetical example in the previous section, Apple charged a lower price and earned

less profit to deter Dell's entry. Business managers often take actions aimed at deterring entry. Some of these actions include advertising to create product loyalty, introducing new products—such as slightly different cereals or toothpastes—to fill market niches, and setting lower prices to keep profits at a level that makes entry less attractive. As we saw in the chapter opener, Apple entered the market for streaming music in 2015. Spotify had hoped to deter Apple's entry by keeping its monthly subscription charge at \$9.99—a price at which it struggled to earn a profit. Apple, however, was willing to match that price and appeared confident that it would be able to earn a profit on its service. **MyEconLab** **Concept Check**

Competition from Substitute Goods or Services

Firms are always vulnerable to competitors introducing a new product that fills a consumer need better than their current product does. Consider the encyclopedia business. For decades, many parents bought expensive and bulky encyclopedias for their children attending high school or college. By the 1990s, computer software companies such as Microsoft were offering electronic encyclopedias that sold for a small fraction of the price of printed encyclopedias. Encyclopedia Britannica and the other encyclopedia publishers responded by cutting prices and launching advertising campaigns aimed at showing the superiority of printed encyclopedias. Still, profits continued to decline, and by the end of the 1990s, most printed encyclopedias had disappeared. Eventually, the free Web site Wikipedia made it difficult for firms to sell even low-priced electronic encyclopedias, and Microsoft and most other firms discontinued producing them. **MyEconLab** **Concept Check**

The Bargaining Power of Buyers

If buyers have enough bargaining power, they can insist on lower prices, higher-quality products, or additional services. Automobile companies, for example, have significant bargaining power in the tire market, which tends to lower tire prices and limit the profitability of tire manufacturers. Some retailers have significant buying power over their suppliers. For instance, Walmart has required many of its suppliers to alter their distribution systems because it wants to reduce the inventories it holds in its warehouses. **MyEconLab** **Concept Check**

The Bargaining Power of Suppliers

If many firms can supply an input and the input is not specialized, the suppliers are unlikely to have the bargaining power to limit a firm's profit. For instance, suppliers of paper napkins to McDonald's restaurants have very little bargaining power. With only a single or a few suppliers of an input, however, the purchasing firm may face a high price. During the 1930s and 1940s, for example, the Technicolor Company was the only producer of the cameras and film that studios needed to produce color movies. Technicolor charged the studios high prices to use its cameras, and it had the power to insist that only its technicians could operate the cameras. The only alternative for the studios was to make black-and-white movies.

As with other competitive forces, the bargaining power of suppliers can change over time. For instance, when IBM chose Microsoft to supply the operating system for its personal computers, Microsoft was a small company with very limited bargaining power. As Microsoft's Windows operating system became standard in more than 90 percent of personal computers, this large market share increased Microsoft's bargaining power. **MyEconLab** **Concept Check**

Can We Predict Which Firms Will Continue to Be Successful?

For years, economists and business strategists believed that market structure was the most important factor in explaining the ability of some firms to continue earning economic profits. For example, most economists argued that during the first few decades after World War II, steel

Although Circuit City's business strategy had once been widely admired, the company declared bankruptcy in 2009.

companies in the United States earned an economic profit because barriers to entry were high, there were few firms in the industry, and competition among firms was low. In contrast, restaurants were seen as less profitable because barriers to entry were low, and the industry was intensely competitive. One problem with this approach to analyzing the profitability of firms is that it does not explain how firms in the same industry can have very different levels of profit.

Today, economists and business strategists put greater emphasis on the characteristics of individual firms and the strategies their managers use to continue to earn economic profits. This approach helps explain why Nucor continues to be a profitable steel company while Bethlehem Steel, at one time the second-largest steel producer in the United States, was forced into bankruptcy. It also explains why Amazon, which began as a small company Jeff Bezos started in Seattle, Washington, with a handful of employees, became the leading online retailer, while many other online retailers that were also started in the 1990s have long since disappeared.

Is it possible to draw general conclusions about which business strategies are likely to be successful in the future? A number of business analysts have tried to identify strategies that have made firms successful and have recommended those strategies to other firms. Although books with these recommendations are often bestsellers, they have a mixed record in identifying winning strategies. For instance, in 1982, Thomas J. Peters and Robert H. Waterman, Jr., published *In Search of Excellence: Lessons from America's Best-Run Companies*. The book was favorably reviewed by business magazines and sold more than 3 million copies. Peters and Waterman identified 43 companies that were the best at using eight key strategies to “stay on top of the heap.” But just two years after the book was published, an article in *BusinessWeek* pointed out that 14 of the 43 companies were experiencing significant financial difficulties. The article noted, “It comes as a shock that so many companies have fallen from grace so quickly—and it also raises some questions. Were these companies so excellent in the first place?”

In 2002, Jim Collins published *Good to Great: Why Some Companies Make the Leap ... and Others Don't*, with the goal of determining how companies can “achieve enduring greatness.” Although this book also sold 3 million copies, not all of the 11 “great companies” it identified were able to remain successful. For instance, Circuit City was forced to file for bankruptcy in 2009, and the Federal National Mortgage Association (“Fannie Mae”) avoided bankruptcy only after the federal government largely took it over in 2008.

These two books, and many others like them, provide useful analyses of the business strategies of successful firms. That many of the firms highlighted in these books are unable to sustain their success should not be surprising. Many successful strategies can be copied—and often improved on—by competitors. Even in oligopolies, competition can quickly erode profits and even turn a successful firm into an unsuccessful one. It remains difficult to predict which currently successful firms will maintain their success.

Economics in Your Life

Why Can't You Find a Cheap PlayStation 4?

At the beginning of this chapter, we asked you to consider why the price of the PlayStation 4 game console is almost the same at every large retailer, from Amazon to Walmart. Why don't these retailers seem to compete on price for this type of product? In this chapter, we have seen that when large firms are engaged in a one-time game of pricing, they are in a prisoner's dilemma and will probably all charge a low price. However, pricing PlayStations is actually a repeated game because the retailers involved will be selling the game system in competition over a long period of time. In this situation, it is more likely that the retailers will arrive at a cooperative equilibrium, in which they will all charge a high price—a result that is good news for the profits of the retailers but bad news for consumers! This analysis is one of many insights that game theory provides into the business strategies of oligopolists.

Conclusion

Firms are locked in a never-ending struggle to earn an economic profit. As we have noted several times, competition erodes economic profits. Even in the oligopolies discussed in this chapter, firms have difficulty earning an economic profit in the long run. We have seen that firms attempt to avoid the effects of competition in various ways. For example, they can occupy a secure niche in the market, they can engage in implicit collusion with competing firms, or they can try to persuade the government impose barriers to entry.

LEARNING OBJECTIVE: Show how barriers to entry explain the existence of oligopolies.

Summary

An **oligopoly** is a market structure in which a small number of interdependent firms compete. **Barriers to entry** keep new firms from entering an industry. The three most important barriers to entry are economies of scale, ownership of a key input, and government barriers. Economies of scale are the most important barrier to entry. **Economies of scale** exist when a firm's long-run average costs fall as it increases output. Government barriers include patents, licensing, and barriers to international trade. A **patent** is the exclusive right to a product for a period of 20 years from the date the patent application is filed with the government.

- 1.3 What do barriers to entry have to do with the extent of competition in an industry? What is the most important reason that some industries, such as music streaming, are dominated by just a few firms?
- 1.4 Give an example of a government-imposed barrier to entry. Why would a government be willing to erect barriers to firms entering an industry?

Problems and Applications

- 1.5 According to an article in *The Economist*, in 2013, regulators in Britain thought that the TSB bank, the United Kingdom, would be successful in shaking up the oligopolistic

British banking market—dominated by Barclays, HSBC, Lloyds Banking Group, and The Royal Bank of Scotland Group—by providing competition to the existing retail-banking market. Do you think the banking market can be considered as an oligopoly? Briefly explain.

According to the article, "Google has said it isn't looking to supplant the big carriers, and Verizon's and AT&T's enormous scale means they can't easily be dislodged."
 - a. What does Google mean that it was not trying to "supplant" the big wireless carriers?

 - b. When the market demand curve intersects the quantity axis at more than 1,000 units but fewer than 10,000 units

c. When the market demand curve intersects the quantity axis at more than 10,000 units

1.9 Alfred Chandler, who was a professor at the Harvard Business School, once observed: “Imagine the diseconomies of scale—the great increase in unit costs—that would

result from placing close to one-fourth of the world’s production of shoes, or textiles, or lumber into three factories or mills!” The shoe, textile, and lumber industries are very competitive, with many firms producing each of these products. Briefly explain how Chandler’s observation helps explain why these industries are competitive.

In some countries, common medicines, like aspirin and cold-medicines, can be sold in any store. However, in many countries, these products can only be sold by licensed pharmacies. Germany is one such country which restricts the sale of all medications to government-licensed pharmacies. Some groups argue that common medications like aspirin and cold-medicine should be available at more stores. Consider what would happen if German regulators decided to allow aspirin to be sold in any store.

- Predict the effect of this decision on the price and quantity of aspirin offered for sale in Germany.
- Can we be sure that the result of the decision will increase the wellbeing of consumers? Briefly explain.

14.2 Game Theory and Oligopoly, pages 534–542

LEARNING OBJECTIVE: Use game theory to analyze the strategies of oligopolistic firms.

Summary

Because an oligopoly has only a few firms, interactions among those firms are particularly important. **Game theory** is the study of how people make decisions in situations in which attaining their goals depends on their interactions with others; in economics, it is the study of the decisions of firms in industries where the profits of each firm depend on its interactions with other firms. A **business strategy** refers to actions taken by a firm to achieve a goal, such as maximizing profit. Oligopoly games can be illustrated with a **payoff matrix**, which is a table that shows the payoffs that each firm earns from every combination of strategies by the firms. One possible outcome in oligopoly is **collusion**, which is an agreement among firms to charge the same price or otherwise not to compete. A **cartel** is a group of firms that collude by agreeing to restrict output to increase prices and profits. In a **cooperative equilibrium**, firms cooperate to increase their mutual payoff. In a **noncooperative equilibrium**, firms do not cooperate but pursue their own self-interest. A **dominant strategy** is a strategy that is the best for a firm, no matter what strategies other firms choose. A **Nash equilibrium** is a situation in which each firm chooses the best strategy, given the strategies chosen by other firms. A situation in which pursuing dominant strategies results in noncooperation that leaves everyone worse off is called a **prisoner’s dilemma**. Because many business situations are repeated games, firms may end up implicitly colluding to

keep prices high. With **price leadership**, one firm takes the lead in announcing a price change, which is then matched by the other firms in the industry.

Review Questions

- Give brief definitions of the following concepts.
 - Game theory
 - Cooperative equilibrium
 - Noncooperative equilibrium
 - Dominant strategy
 - Nash equilibrium
 - Price leadership
- Why is game theory needed to study oligopolies, but not perfectly competitive markets?
- What is the difference between explicit collusion and implicit collusion? Give an example of each.
- What is a prisoner’s dilemma game? Is the outcome of the game likely to be different in a repeated game? Briefly explain.

Problems and Applications

- 2.5 Bob and Tom are two criminals who have been arrested for burglary. The police put Tom and Bob in separate cells. They offer to let Bob go free if he confesses to the crime and testifies against Tom. Bob also is told that he will serve a 15-year sentence if he remains silent while Tom confesses. If Bob confesses and Tom also confesses, they will each serve a 10-year sentence. Separately, the police make the same offer to Tom. Assume that Bob and Tom know that if they both remain silent, the police have only enough evidence to convict them of a lesser crime, and they will both serve 3-year sentences.
- Use the information provided to write a payoff matrix for Bob and Tom.
 - Does Bob have a dominant strategy? If so, what is it?
 - Does Tom have a dominant strategy? If so, what is it?
 - What sentences do Bob and Tom serve? How might they have avoided this outcome?
- 2.6 Explain how collusion makes firms better off. Given the incentives to collude, briefly explain why every industry doesn't become a cartel.
- 2.7 Many American universities offer "early decision" admissions plans. Under such plans, students first apply early to only one university and, if they are accepted, they must enroll in that university and may not apply to any other university. Some critics of early decision plans, including some university officials, argue that the plans put too much pressure on students to decide early which university to attend. Some university administrators have proposed abolishing early decision plans, but as one newspaper headline put it: "Applicants Continue to Flock to Early Admission Programs." If many universities believe that early decision plans should be abolished, why do they continue to use them? Can game theory help analyze this situation? Briefly explain.

- 2.10 (Related to **Solved Problem 14.2 on page 536**) Coop and Migros are the two largest department stores in

Switzerland. Each store also offers credit card products to its customers. Both firms occasionally consider raising the annual membership rate for their credit cards. Such coordinated higher rates would likely increase the profits of both firms. However, neither company raises its rates. Use a payoff matrix to illustrate why the firms probably choose not to raise rates. Assume that the two firms form a duopoly in the market and that the choices they face are to "Raise rates" or to "Not raise rates."

- 2.11 (Related to **Solved Problem 14.2 on page 536**) Coca-Cola and Pepsi both advertise aggressively, but would they be better off if they didn't? Their commercials are usually not designed to convey new information about their products. Instead, they are designed to capture each other's customers. Construct a payoff matrix using the following hypothetical information:
- If neither firm advertises, Coca-Cola and Pepsi each earn a profit of \$750 million per year.
 - If both firms advertise, Coca-Cola and Pepsi each earn a profit of \$500 million per year.
 - If Coca-Cola advertises and Pepsi doesn't, Coca-Cola earns a profit of \$900 million, and Pepsi earns a profit of \$400 million.
 - If Pepsi advertises and Coca-Cola doesn't, Pepsi earns a profit of \$900 million, and Coca-Cola earns a profit of \$400 million.

- 2.13 World War I began in August 1914 and on the Western Front quickly bogged down into trench warfare. In Belgium and northern France, British and French troops were dug into trenches facing German troops a few hundred yards away. The troops continued firing back and forth until a remarkable event occurred, which historians have labeled "The Christmas Truce." On Christmas Eve, along several sectors of the front, British and German troops stopped firing and eventually came out into the area between the trenches to sing Christmas carols and exchange small gifts. The truce lasted until Christmas night in most areas of the front, although it continued until New Year's Day in a few areas. Most of the troops' commanding officers were unhappy

with the truce—they would have preferred the troops to keep fighting through Christmas—and in the future they often used a policy of rotating troops around the front so that the same British and German troops did not face each other for more than relatively brief periods. Can game theory explain why the Christmas Truce occurred? Can game theory help explain why the commanding officers' strategy was successful in reducing future unauthorized truces?

2.14 Australia's grocery market is dominated by a duopoly of two nationwide chains, Coles and Woolworths. IGA, a relatively new entrant, plans to offer a price-matching promotion. Under this promotion, IGA will match the lower of the prices charged by Coles and Woolworth stores on any item. An IGA spokesman commented on the company's policy by saying it will appeal to "time poor" consumers. Explain how this strategy is designed to attract customers away from other stores.

2.15 (Related to the Making the Connection on page 539) In 2015, the U.S. Department of Justice was investigating whether the four major U.S. airlines were colluding by restraining increases in capacity with the goal of avoiding price cutting. An airline industry analyst commented on the investigation, "I don't sense that the executives talk to each other. They actually hate each other, truth be told. But with so few of them left, there's almost a natural oligopoly."

2.16 (Related to the Making the Connection on page 539) Airlines sometimes find themselves in price wars. Consider the following game: Delta and United are the only two airlines flying the route from Houston to Omaha. Each firm has two strategies: charge a high price or charge a low price.

		United	
		High	Low
Delta	High	Delta earns \$20,000 United earns \$20,000	Delta earns -\$10,000 United earns \$30,000
	Low	Delta earns \$30,000 United earns -\$10,000	Delta earns \$0 United earns \$0

- Is this game a prisoner's dilemma?
- How could repeated playing of the game change the strategy each firm uses?

For many years, airlines would post proposed changes in ticket prices on computer reservation systems several days before the new ticket prices went into effect. Eventually, the federal government took action to end this practice. Now airlines can post prices on their reservation systems only for tickets that are immediately available for sale. Why would the federal government object to the old system of posting prices before they went into effect?

2.18 Finding dominant strategies is often a very effective way of analyzing a game. Consider the following game: Microsoft and Apple are the two firms in the market for operating systems. Each firm has two strategies: charge a high price or charge a low price.

		Apple	
		High	Low
Microsoft	High	Microsoft earns \$1 billion Apple earns \$6 billion	Microsoft earns \$10 billion Apple earns \$6 billion
	Low	Microsoft earns \$8 billion Apple earns \$2 billion	Microsoft earns \$4 billion Apple earns \$3 billion

2.19 Suppose there are four large manufacturers of toilet tissue. The largest of these manufacturers announces that it will raise its prices by 15 percent due to higher paper costs. Within three days, the other three large toilet tissue manufacturers announce similar price hikes. Would this decision to raise prices be evidence of explicit collusion among the four companies? Briefly explain.

2.20 In the United Kingdom there are a few dominant supermarket chains, such as Asda, Marks & Spencer's, Sainsbury's, and Tesco. The BBC recently mentioned the expression "supermarket price war" when writing about this particular market.

14.3 Sequential Games and Business Strategy, pages 542–546
LEARNING OBJECTIVE: Use sequential games to analyze business strategies.

Summary

Recent work in game theory has focused on actions firms can take to deter the entry of new firms into an industry. Detering entry can be analyzed using a sequential game, where first one

firm makes a decision and then another firm reacts to that decision. Sequential games can be illustrated using decision trees.

14.4 The Five Competitive Forces Model, pages 542–549

LEARNING OBJECTIVE: Use the five competitive forces model to analyze competition in an industry.

Summary

Michael Porter of the Harvard Business School argues that the state of competition in an industry is determined by five competitive forces: competition from existing firms, the threat from new entrants, competition from substitute goods or services, the bargaining power of buyers, and the bargaining power of suppliers.

A Monopoly on Lobster Dinners in Maine?

A *New York Times* article written from Stonington, Maine, explained, “Lobsters are flooding the market here.” The reporter observed that the huge lobster harvest was not good news for fishermen because “the law of supply and demand has forced the price down to a 40-year low” of \$1.35 per pound. Yet shortly after this article appeared, a columnist for *Slate*, an online magazine, had dinner with his father at the only lobster restaurant in Stonington, The Fisherman’s Friend. He was surprised that the restaurant charged \$20.99 for each dinner.

How could The Fisherman’s Friend charge so much for a lobster dinner when the price of lobsters was so low? The answer is that The Fisherman’s Friend is the *only* seafood restaurant in Stonington. The *Slate* reporter and his father couldn’t eat at “the competitor next door” because there wasn’t one. To eat lobster while staying in Stonington, they had to eat at that restaurant or buy lobsters in a supermarket and

cook them. In other words, The Fisherman’s Friend has a *monopoly* on selling seafood dinners in that town.

Few firms in the United States are monopolies because in a market system whenever a firm earns an economic profit, typically other firms will enter that market. Therefore, it is very difficult for a firm to remain the only provider of a good or service. Only if the gap between the price of lobsters and the price of lobster dinners in Stonington fails to attract a competitor would The Fisherman’s Friend be able to maintain its monopoly. Although not common, monopolies are worth studying because they provide a benchmark for how firms behave when they face little or no competition. In this chapter, we will build a model to analyze monopolies.

Economics in Your Life

Can a Business Run from Your Dorm Be a Monopoly?

You and your roommate Fatma hear students complaining about the lack of food services on campus on Saturday and Sunday evenings, so you come up with an idea for a business: You will buy rolls, lunch meat, lettuce, and tomatoes and become the sole seller of submarine sandwiches in your school’s dormitories on those evenings. You believe that there will be many hungry customers when students return to campus from the library and off-campus events. What price will you charge for the subs?

Fatma argues that because your business is a monopoly, you can charge prices much higher than what local shops charge for subs during the day; hungry students will have to buy your subs or stay hungry until the following day. You want to make a profit from your business but are not sure whether Fatma is right. Is your business a monopoly? Should you charge high prices for your subs? As you read this chapter, try to answer these questions. You can check your answers against those we provide on **page 581** at the end of this chapter.

Although few firms are monopolies, the economic model of monopoly can be quite useful. As we have seen, even though perfectly competitive markets are rare, the competitive market model provides a benchmark for how a firm acts in the most competitive situation possible: when it is in an industry, such as farming, with many firms that all supply the same product. Monopoly provides a benchmark for the other extreme, where a firm is the only one in its market and, therefore, faces no competition from other firms supplying its product. The monopoly model is also useful in analyzing situations in which firms agree to *collude*, or not compete, and act together as if they were a monopoly. As we will discuss in this chapter, collusion is illegal in the United States, but it occasionally happens.

Monopolies pose a dilemma for the government. Should the government allow monopolies to exist? Are there circumstances in which the government should actually promote the existence of monopolies? Should the government regulate the prices monopolies charge? If so, will such price regulation increase economic efficiency? In this chapter, we will explore these public policy issues.

15.1 Is Any Firm Ever Really a Monopoly?

LEARNING OBJECTIVE: Define monopoly.

Monopoly A firm that is the only seller of a good or service that does not have a close substitute.

A **monopoly** is a firm that is the only seller of a good or service that does not have a close substitute. Because substitutes of some kind exist for just about every product, are there actually any monopolies? The answer is “yes,” provided that the substitutes are not “close” substitutes. But how do we decide whether a substitute is a close substitute? A narrow definition of monopoly that some economists use is that a firm has a monopoly if it can ignore the actions of all other firms. In other words, if a firm can ignore the prices other firms charge, it has a monopoly because other firms must not be producing close substitutes. For example, candles are a substitute for electric lights, but your local electric company can ignore candle prices because however low the price of candles becomes, almost no customers will give up using electric lights and switch to candles. Therefore, your local electric company is clearly a monopoly.

Many economists, however, use a broader definition of *monopoly*. For example, consider again The Fisherman’s Friend seafood restaurant in Stonington, Maine, that we discussed in the chapter opener. Does this restaurant have a monopoly? Substitutes for lobster dinners certainly exist. If the price of lobster dinners is too high, people will switch to steak dinners or spaghetti dinners or some other food. People do not have to eat at The Fisherman’s Friend or starve. The restaurant is in competition with several other local restaurants. So, The Fisherman’s Friend does not meet the narrow definition of a monopoly. Many economists, however, would still argue that it is useful to think of the restaurant as having a monopoly.

Although steak and spaghetti are substitutes for lobster, competition from firms selling them is not enough to keep The Fisherman’s Friend from earning an economic profit. We have seen that when firms earn an economic profit, we can expect new firms to enter the industry, and in the long run, the economic profit is competed away (see Chapter 12). The Fisherman’s Friend’s profit will not be competed away as long as it is the *only* seller of lobster dinners. The reporter mentioned in the chapter opener noted, “Stonington is a great place to visit. But it’s also a very small town.” So it’s possible that no other seafood restaurants will choose to open in the town. In that case, using the broader definition of monopoly, The Fisherman’s Friend has a monopoly because there are no other firms selling a substitute close enough that its economic profit will be competed away in the long run.

Is the NCAA a Monopoly?

In 1905, President Theodore Roosevelt was disturbed by the 18 deaths and many injuries college football players had suffered during the previous season. A meeting took place at the White House between Roosevelt and several college

presidents to discuss rule changes that would make the game safer. This meeting eventually led to the establishment of the National Collegiate Athletic Association (NCAA) in 1910. NCAA rules now govern men's and women's athletics at more than 1,200 institutions. On its Web site, the NCAA states, "The National Collegiate Athletic Association is a membership-driven organization dedicated to safeguarding the well-being of student-athletes and equipping them with the skills to succeed on the playing field, in the classroom and throughout life." Some economists wonder whether the NCAA's rules might also have other goals.

Harvard University economist Robert Barro claims that the NCAA is effectively a monopoly. Nearly all colleges want their teams to participate in NCAA tournaments and other events. Those colleges therefore have to agree to the NCAA's rules. Included in those rules are limits on the number of scholarships that a college can award student athletes and a prohibition on paying salaries to athletes. These restrictions reduce the cost to colleges of running their athletic programs. Noting that very few college athletes go on to careers in professional sports, Barro argues that "many college basketball players come from poor families... Absent the NCAA, such a student would be able to amass significant cash during a college career. With the NCAA in charge, this student remains poor." The NCAA defends its restrictions on scholarships and its prohibition on paying salaries to athletes as a way of preserving the amateur status of collegiate sports.

Because the NCAA does not directly control the operations of the athletic departments of the member colleges, some economists argue that it is better to think of the organization as a cartel than as a monopoly. As we saw in Chapter 13, when discussing the Organization of the Petroleum Exporting Countries (OPEC), a cartel is a group of firms that collude by agreeing to restrict output to increase prices and profits. The NCAA restricts the number of games the member schools' teams can play, effectively restricting output. For decades, the NCAA also restricted the number of college football and basketball games that could be televised. Some larger schools did not support these restrictions, however, and in 1982, the University of Georgia and the University of Oklahoma sued the NCAA under the federal antitrust laws. As we will see in Section 15.5, the antitrust laws are aimed at eliminating collusion and promoting competition among firms. In 1984, the Supreme Court decided the case against the NCAA, noting that "good motives alone will not validate an otherwise anticompetitive practice." Following the decision, college football and basketball broadcasts have greatly increased.

In 2014, the NCAA was the subject of two antitrust lawsuits related to video games. The NCAA reached a settlement in which it agreed to pay a total of \$20 million to 100,000 current and former athletes whose names or images had been used in NCAA-branded videogames. In a separate lawsuit, a federal court judge ruled in favor of former University of California, Los Angeles, basketball player Ed O'Bannon, who argued that he should have received compensation after his image was used in an NCAA-branded video game. The judge handed down a broad ruling that, if upheld by the U.S. Supreme Court, would allow colleges to compensate current athletes for their appearances both in video games and on television. The NCAA also agreed to allow the five most successful conferences—the Southeastern Conference, the Atlantic Coast Conference, the Pacific-12, the Big Ten, and the Big 12—more freedom to determine the compensation they would give athletes.

The NCAA's defenders argue that its rules and restrictions are necessary to preserve the ideal of amateurism in college sports, and to make it possible for colleges to offer students the opportunity to participate in sports that do not generate much revenue from ticket sales and broadcasting rights, while preserving the ability of smaller schools to compete with larger schools. The organization's critics believe that many of

15.2 Where Do Monopolies Come From?

LEARNING OBJECTIVE: Explain the four main reasons monopolies arise.

Because monopolies do not face competition, every firm would like to have a monopoly. But to have a monopoly, barriers to entering the market must be so high that no other firms can enter. *Barriers to entry* may be high enough to keep out competing firms for four main reasons:

1. Government action blocks the entry of more than one firm into a market.
2. One firm has control of a key resource necessary to produce a good.
3. There are important *network externalities* in supplying the good or service.
4. Economies of scale are so large that one firm has a *natural monopoly*.

Government Action Blocks Entry

As we will discuss later in this chapter, governments ordinarily try to promote competition in markets, but sometimes governments take action to block entry into a market. In the European Union (EU), governments of the 28 EU-member nations block entry using two different methods:

1. Giving a firm the exclusive legal right to produce a good by granting it a *patent*, *copyright*, or *trademark*.
2. Giving a firm the exclusive legal right to produce a service by granting it a franchise.

Patent The exclusive right to a product for a period of 20 years from the date the patent application is filed with the government.

Patents, Copyrights, and Trademarks In 2013, only 25 EU-member nations signed the agreement on a Unified Patent Court (UPC), laying the foundation for unitary patent protection in the European Union (EU). After entry into force in 2017, the proprietor of a European patent will be able to get patent protection in 25-member states of the EU. Currently, either the European Patent Office (EPO) or individual patent offices of EU jurisdictions grants patents that protect new products within the EU-25 for a period of 20 years from the date the patent is filed. Without patents, firms would not be interested in the research and development necessary for the development of new products. The fact that a multinational firm like Siemens was allowed to patent 4,300 inventions in 2015, explains why it hired 28,800 researchers and spent €4.4 billion on research and development.

Patents are especially imperative to pharmaceutical firms that spend substantial time and money to develop new drugs. In the EU, a medicine is only marketed after receiving authorization from either individual national authorization agencies or from the European Commission's European Medicines Agency. The former authorizes medicines for use within the national territories of EU-member states, while the latter is a centralized procedure that provides a single marketing authorization valid throughout the EU-28. On average, it takes 12 years to test a new medicine before it is considered safe to sell in the EU. This means that the firm should apply for an early patent to avoid risks that rival firms would develop the drug first.

The maximum period of a European patent protection is 20 years from its filing date, but in some cases the period of protection may be extended against extra fees. After the expiry of the patent, it becomes a generic drug and other firms are allowed to

chemically replicate it. This causes an increase in competition and a decline in the sales revenue of the original drug. In some cases where a disease is widespread in a certain country, a compulsory license is legally granted without the patent owner's consent, allowing other firms to produce cheaper bio-similar versions of the drug oftentimes against a payment that is set through arbitration. But firms are not allowed to export or outsource the drug production. In 2012, the Indian Patent Office (IPO) issued its first compulsory license that allowed an Indian pharmaceutical firm (Natco) to produce a low priced version of Nexavar, a kidney cancer drug developed by Bayer AG. This has substantially affected the sales of Bayer's drug in India.

In the EU, firms register trademarks or brand names either nationally or under an EU Community Trademark that protects the firms' rights in the 28-member countries of the EU. The European Council explains that "trade mark may consist of any signs capable of being represented graphically, particularly words, including personal names, designs, letters, numerals, the shape of goods or of their packaging, provided that such signs are capable of distinguishing the goods or services of one undertaking from those of other undertakings." Nestlé is one of the firms that vigorously defend their trademarks and has registered KitKat's shape in 2006. In 2013, Nestlé won a lawsuit against Cadbury, preserving its rights to the candy four-bar's shape.

Does Hasbro Have a Monopoly on Monopoly?

To receive a copyright, patent, or trademark, a work has to be substantially new. Once a work no longer has legal protection, it is in the *public domain* and available to be freely used. It wouldn't be possible, for example, to make small changes to Mark Twain's novel *Huckleberry Finn* and then claim copyright on the book because it has been in the public domain for decades. (If you drew new illustrations for the book, however, it would be possible to copyright those illustrations independently of the text of the book.)

Hasbro is the multinational U.S. company that owns Monopoly, one of the world's most popular board games. The company estimates that more than 275 million copies of the game have been sold, and it is available in 43 languages. According to Hasbro, Charles Darrow invented the game in the 1930s. After selling many homemade copies, Darrow sold the game to Parker Brothers. In 1935, the U.S. Patent and Trademark Office issued Parker Brothers a trademark on the use of the name Monopoly for a board game. Hasbro bought Parker Brothers in 1991. Trademarks, unlike patents and copyrights, never expire, so Hasbro continues to have a trademark on the name Monopoly.

Economics professor Ralph Anspach of California State University, San Francisco, received an unexpected lesson in the law of trademarks when he decided in the 1970s to sell a game about competition that he titled *Anti-Monopoly*. The game was a hit, selling 200,000 copies the first year. Parker Brothers sued Anspach, though, on the grounds that his game infringed on its Monopoly trademark. In the course of defending the lawsuit, Anspach believed he had uncovered evidence that in 1904, a woman named Elizabeth Magie had developed *The Landlord's Game*, which was very similar to Monopoly. The game was never trademarked and was played for years on the East Coast. According to Anspach, Darrow became aware of *The Landlord's Game* in the mid-1930s, made a few changes to it, and sold it to Parker Brothers in 1935. A federal appeals court largely agreed with Anspach that given the history of the game, the name Monopoly was in the public domain and so couldn't be trademarked. Congress later amended the law, though, in a way that reinstated the Parker Brothers trademark. Eventually, Anspach and Hasbro worked out a settlement under which Anspach was allowed to sell his *Anti-Monopoly* game under a license from Hasbro.

Losing the trademark on its Monopoly game would have cost Hasbro millions of dollars per year because other companies could have begun to market similar games using the same title. The long legal fight the company had with Professor Anspach

Hasbro's trademark on its Monopoly game prevents other companies from creating and selling similar games using the same title.

illustrates that companies consider it critical to retain exclusive control over their products.

Copyright A government-granted exclusive right to produce and sell a creation.

Public franchise A government designation that a firm is the only legal provider of a good or service.

Akin to patent and trademark protection, governments grant new books, films, performances, and music **copyright** protection as a means of enhancing creativity. The **Copyright Law of the European Union** harmonizes various copyright laws of the EU and obliges member states to enact directives into their national laws. While the EU authors’ rights last for 70 years after their death, the rights of EU performers, producers of phonograms and films, and broadcasting organizations last for 50 years from the distribution or communication of the performance.

Public Franchises Sometimes governments award **public franchises** that restrict a public utility market to a single firm, normally through a competitive process. For example, Great Britain franchises passenger railway services to private companies for a designated period.

In other cases when the government wants to help consumers by keeping prices low, and possibly subsidizing them, it would choose to provide the service directly to the public through *public enterprises*. This type of public ownership is quite common for natural monopolies of vital public utilities such as electricity, natural gas, water, and sewage services. Public enterprises are widespread in many European nations and emerging economies and the attempts to privatize some of these enterprises has raised ire in these nations.

MyEconLab Concept Check

Control of a Key Resource

Firms are also allowed to control key resources, especially in the case of natural monopolies. Since there are many competitors in these sectors, the control is usually granted for specific geographic areas. The Middle East is well-known to be a major producer of oil and natural gas. Due to the high exploration and development costs, governments grant firms complete control of the exploration and production in designated areas.

Eni S.p.A. is an Italian multinational oil and gas company that has complete control of oil and gas exploration in the Egyptian Mediterranean north coast. However, the Egyptian government grants it only 50 percent stake in the production, with the remaining 50 percent held by an Egyptian state-owned oil and gas company. Conversely, while oil and gas companies in Kuwait have control over specific fields, the Kuwaiti government publicly owns all of these oil and gas companies. Hence, in principle the Kuwaiti government owns around 40 percent of GDP in the nation.

The largest stadium in England is Wembley Stadium, which is owned by the Football Association. It hosts major football games, such as home matches of the England national football team. The popularity of football stipulates that every Premier League club has its own stadium, meaning that each season Premier League games will be hosted by a total of 20 stadiums. Control of these stadiums is considered as a barrier that could limit entry to teams with large stadiums.

Are Diamond Profits Forever? The De Beers Diamond Monopoly

The most famous monopoly based on control of a raw material is the De Beers diamond mining and marketing company of South Africa. Before the 1860s, diamonds were extremely rare. Only a few pounds of diamonds were produced each year, primarily from Brazil and India. Then in 1870,

enormous deposits of diamonds were discovered along the Orange River in South Africa. It became possible to produce thousands of pounds of diamonds per year, and the owners of the new mines feared that the price of diamonds would plummet. To avoid financial disaster, the mine owners decided in 1888 to merge and form De Beers Consolidated Mines, Ltd.

De Beers became one of the most profitable and longest-lived monopolies in history. The company carefully controlled the supply of diamonds to keep prices high. As new diamond deposits were discovered in Russia and Zaire, De Beers was able to maintain prices by buying most of the new supplies.

Because diamonds are rarely destroyed, De Beers has always worried about competition from the resale of stones. Heavily promoting diamond engagement and wedding rings with the slogan “A Diamond Is Forever” was a way around this problem. Because engagement and wedding rings have great sentimental value, they are seldom resold, even by the heirs of the original recipients. De Beers advertising has been successful even in some countries, such as Japan, that have had no custom of giving diamond engagement rings. As the populations in De Beers’s key markets age, its advertising in recent years has focused on middle-aged men presenting diamond rings to their wives as symbols of financial success and continuing love, and on women buying “right-hand rings” for themselves.

Over the years, competition has gradually increased in the diamond business. By 2000, De Beers directly controlled only about 40 percent of world diamond production. The company became concerned about how much it was spending to buy diamonds from other sources to keep them off the market. It decided to abandon its strategy of attempting to control the worldwide supply of diamonds and to concentrate instead on differentiating its diamonds by relying on its name recognition. Each De Beers diamond is now marked with a microscopic brand—a “Forevermark”—to reassure consumers of its high quality. Other firms, such as BHP Billiton, which owns mines in northern Canada, have followed suit by branding their diamonds. Whether consumers will pay attention to brands on diamonds remains to be seen, although through 2015, the branding strategy had helped De Beers to maintain about a 35 to 40 percent share of the diamond market.

Network Externalities

There are **network externalities** in the consumption of a product if its usefulness increases with the number of people who use it. If you owned the only HD television in the world, for example, it would not be very valuable because firms would not have an incentive to develop HD programming. The more HD televisions there are in use, the more valuable they become to consumers.

Some economists argue that network externalities can serve as barriers to entry. For example, in the early 1980s, Microsoft gained an advantage over other software companies by developing MS-DOS, the operating system for the first IBM personal computers. Because IBM sold more computers than any other company, software developers wrote many application programs for MS-DOS. The more people who used MS-DOS-based programs, the greater the value to a consumer of using an MS-DOS-based program. By the 1990s, Microsoft had replaced MS-DOS with Windows. Today, Windows has an 85 percent share in the market for personal computer operating systems, with Apple’s operating system having a 10 percent share, and other operating

Network externalities A characteristic of a product in which its usefulness increases with the number of consumers who use it.

systems, including the open-source Linux system, having shares of about 1 percent or less. If another firm introduced a new operating system, some economists argue that relatively few people would use it initially, and few applications would run on it, which would limit the operating system's value to other consumers.

eBay was the first Internet site to attract a significant number of people to its online auctions. Once many people began to use eBay to buy and sell collectibles, antiques, and many other products, it became a more valuable place to buy and sell. Yahoo.com, Amazon.com, and other Internet sites eventually started online auctions, but they had difficulty attracting buyers and sellers. On eBay, a buyer expects to find more sellers, and a seller expects to find more potential buyers than on Amazon or other auction sites.

As these examples show, from a firm's point of view, network externalities can set off a *virtuous cycle*: If a firm can attract enough customers initially, it can attract additional customers because the value of its product has been increased by more people using it, which attracts even more customers, and so on. With products such as computer operating systems and online auctions, it might be difficult for new firms to enter the market and compete away the profit being earned by the first firm in the market.

Economists debate, however, the extent to which network externalities are important barriers to entry in the business world. Some economists argue that Microsoft and eBay have dominant positions primarily because they are efficient in offering products that satisfy consumer preferences rather than because of the effects of network externalities. In this view, the advantages firms gain from network externalities would not be enough to protect them from competing firms offering better products. For example, many people have switched from computers to tablets and smartphones that run on Apple's iOS or Google's Android operating system, making Microsoft's domination of computer operating systems less important. Natural Monopoly

Economies of scale exist when a firm's long-run average cost falls as it increases the quantity of output it produces (see Chapter 11). A **natural monopoly** occurs when economies of scale are so large that one firm can supply the entire market at a lower average total cost than can two or more firms. In that case, there is "room" in the market for only one firm.

Figure 15.1 shows the average total cost curve for a firm producing electricity and the total demand for electricity in the firm's market. Notice that the average total

Natural monopoly A situation in which economies of scale are so large that one firm can supply the entire market at a lower average total cost than can two or more firms.

MyEconLab Animation

Figure 15.1

Average Total Cost Curve for a Natural Monopoly

With a natural monopoly, the average total cost curve is still falling when it crosses the demand curve (point A). If only one firm is producing electric power in the market, and it produces where the average cost curve intersects the demand curve, average total cost will equal \$0.04 per kilowatt-hour of electricity produced. If the market is divided between two firms, each producing 15 billion kilowatt-hours, the average cost of producing electricity rises to \$0.06 per kilowatt-hour (point B). In this case, if one firm expands production, it can move down the average total cost curve, lower its price, and drive the other firm out of business.

cost curve is still falling when it crosses the demand curve at point A. If the firm is a monopoly and produces 30 billion kilowatt-hours of electricity per year, its average total cost of production will be \$0.04 per kilowatt-hour. Suppose instead that two firms are in the market, each producing half the market output, or 15 billion kilowatt-hours per year. Assume that each firm has the same average total cost curve. The figure shows that producing 15 billion kilowatt-hours would move each firm back up its average cost curve so that the average cost of producing electricity would rise to \$0.06 per kilowatt-hour (point B). In this case, if one of the firms expands production, it will move down the average total cost curve. With lower average costs, it will be able to offer electricity at a lower price than the other firm can offer. Eventually, the other firm will be driven out of business, and the remaining firm will have a monopoly. Because a monopoly would develop automatically—or *naturally*—in this market, it is a natural monopoly.

Natural monopolies are most likely to occur in markets where fixed costs are very large relative to variable costs. For example, a firm that produces electricity must make a substantial investment in machinery and equipment necessary to generate the electricity and in the wires and cables necessary to distribute it. Once the firm makes the initial investment, however, the marginal cost of producing another kilowatt-hour of electricity is relatively small.

MyEconLab Concept Check

15.3 How Does a Monopoly Choose Price and Output?

LEARNING OBJECTIVE: Explain how a monopoly chooses price and output.

Like every other firm, a monopoly maximizes profit by producing where marginal revenue equals marginal cost. A monopoly differs from other firms in that *a monopoly's demand curve is the same as the market demand curve for the product*. When discussing perfect competition, we emphasized that the market demand curve for wheat was very different from the demand curve for the wheat produced by any one farmer (see Chapter 12). If, however, one farmer had a monopoly on wheat production, the two demand curves would be exactly the same.

Marginal Revenue Once Again

Recall that firms in perfectly competitive markets—such as a farmer in the wheat market—face horizontal demand curves. These firms are *price takers*. All other firms, including monopolies, are *price makers*. If price makers raise their prices, they will lose some, but not all, of their customers. Therefore, they face both a downward-sloping demand curve and a downward-sloping marginal revenue curve. Let's review why a firm's marginal revenue curve slopes downward if its demand curve slopes downward.

Remember that when a firm cuts the price of a product:

- **One good thing happens.** The firm sells more units of the product.
- **One bad thing happens.** The firm receives less revenue from each unit than it would have received at the higher price.

For example, consider the table in Figure 15.2, which shows information on the market for Comcast's basic cable package. To operate a cable system in a city, firms typically need a license from the city government. Comcast is the only cable television available in some cities. For simplicity, we assume that a particular market has only 10 potential subscribers. If Comcast charges a price of \$60 per month, it won't have any subscribers. If it charges a price of \$57, it sells 1 subscription. At \$54, it sells 2 subscriptions, and so on. Comcast's total revenue is equal to the number of subscriptions sold per month multiplied by the price. The firm's average revenue—or revenue per subscription sold—is equal to its total revenue divided by the quantity of subscriptions sold. Comcast is particularly interested in marginal revenue because marginal revenue tells the firm how much its revenue will increase if it cuts the price to sell one more subscription.

Subscribers per Month (Q)	Price (P)	Total Revenue (TR = P x Q)	Average Revenue (AR = TR/Q)	Marginal Revenue (MR = $\Delta TR/\Delta Q$)

Figure 15.2

Calculating a Monopoly's Revenue

Comcast Cable faces a downward-sloping demand curve for subscriptions to basic cable. To sell more subscriptions, it must cut the price. When this happens, it gains revenue from selling more subscriptions but loses revenue from selling at a lower price the subscriptions that it could have sold at a higher price. The firm's marginal revenue is the change in revenue from selling another subscription. We can calculate marginal revenue by subtracting the revenue lost as a result of a price cut from the revenue gained. The table shows that Comcast's marginal revenue is less than the price for every subscription sold after the first subscription. Therefore, Comcast's marginal revenue curve will be below its demand curve.

Notice that Comcast's marginal revenue is less than the price for every subscription sold after the first subscription. To see why, think about what happens if Comcast cuts the price of its basic cable package from \$42 to \$39, which increases its subscriptions sold from 6 to 7. Comcast increases its revenue by the \$39 it receives for the seventh subscription. But it also loses revenue of \$3 per subscription on the first 6 subscriptions because it could have sold them at the old price of \$42. So, its marginal revenue on the seventh subscription is $\$39 - \$18 = \$21$, which is the value shown in the table. The graph in Figure 15.2 plots Comcast's demand and marginal revenue curves, based on the information in the table.

MyEconLab Concept Check

MyEconLab Animation

Figure 15.3 Profit-Maximizing Price and Output for a Monopoly

Panel (a) shows that to maximize profit, Comcast should sell subscriptions up to the point where the marginal revenue from selling the last subscription equals its marginal cost (point A). In this case, both the marginal revenue from selling the sixth subscription and the marginal cost are \$27. Comcast maximizes profit by selling 6 subscriptions per month

and charging a price of \$42 (point B). In panel (b), the green rectangle represents Comcast's profit. The rectangle has a height equal to \$12, which is the price of \$42 minus the average total cost of \$30, and a base equal to the quantity of 6 cable subscriptions. Comcast's profit therefore equals $12 \times 6 = \$72$.

Profit Maximization for a Monopolist

Figure 15.3 shows how Comcast combines the information on demand and marginal revenue with information on average and marginal costs to decide how many subscriptions to sell and what price to charge. We assume that the firm's marginal cost and average total cost curves have the usual U shapes we encountered in previous chapters (see Chapters 11 and 12). In panel (a), we see how Comcast can calculate its profit-maximizing quantity and price. As long as the marginal cost of selling one more subscription is less than the marginal revenue, the firm should sell additional subscriptions because it is adding to its profit. As Comcast sells more cable subscriptions, rising marginal cost will eventually equal marginal revenue, and the firm will be selling the profit-maximizing quantity of subscriptions. Comcast maximizes profit with the sixth subscription, which adds \$27 to the firm's costs and \$27 to its revenues—point A in panel (a) of Figure 15.3. The demand curve indicates that Comcast can sell 6 subscriptions for a price of \$42 per month. We can conclude that Comcast's profit-maximizing quantity of subscriptions is 6, and its profit-maximizing price is \$42.

Panel (b) shows that the average total cost of 6 subscriptions is \$30 and that Comcast can sell 6 subscriptions at a price of \$42 per month (point B on the demand curve). Comcast is making a profit of \$12 per subscription—the price of \$42 minus the average cost of \$30. Its total profit is \$72 ($= 6 \text{ subscriptions} \times \$12 \text{ profit per subscription}$), which is shown by the area of the green-shaded rectangle in the figure. We could also have calculated Comcast's total profit as the difference between its total revenue and its total cost. Its total revenue from selling 6 subscriptions is \$252. Its total cost equals its average total cost multiplied by the number of subscriptions sold, or $\$30 \times 6 = \180 . So, its profit is $\$252 - \$180 = \$72$.

Note that even though Comcast is earning an economic profit, new firms will *not* enter the market unless they can obtain licenses from the city. If it holds the only license, Comcast has a monopoly and will not face competition from other cable operators. Therefore, if other factors remain unchanged, Comcast will be able to continue to earn an economic profit, even in the long run.

Solved Problem 15.3

MyEconLab Interactive Animation

Finding the Profit-Maximizing Price and Output for a Cable Monopoly

Suppose that Comcast has a cable monopoly in Philadelphia. The following table gives Comcast's demand and cost per month for subscriptions to basic cable (for simplicity,

we once again keep the number of subscribers artificially small):

Price	Quantity	Total Revenue	Marginal Revenue ($MR = \frac{\Delta TR}{\Delta Q}$)	Total Cost	Marginal Cost ($MC = \frac{\Delta TR}{\Delta Q}$)
\$27	3			\$56	
26	4			73	
25	5			91	
24	6			110	
23	7			130	
22	8			151	

- Fill in the missing values in the table.
- If Comcast wants to maximize profit, what price should it charge, and how many cable subscriptions per month should it sell? How much profit will Comcast make? Briefly explain.
- Suppose the local government imposes a \$25-per-month tax on Comcast. Now what price should Comcast charge, how many subscriptions should it sell, and what will its profit be?

Solving the Problem

Step 1: Review the chapter material. This problem is about finding the profit-maximizing quantity and price for a monopolist, so you may want to review the section "Profit Maximization for a Monopolist," which begins on page 567.

Step 2: Answer part (a) by filling in the missing values in the table. Remember that to calculate marginal revenue and marginal cost, you divide the change in total revenue or total cost by the change in quantity.

We don't have enough information from the table to fill in the values for marginal revenue and marginal cost in the first row.

Price	Quantity	Total Revenue	Marginal Revenue ($MR = \frac{\Delta TR}{\Delta Q}$)	Total Cost	Marginal Cost ($MC = \frac{\Delta TR}{\Delta Q}$)
\$27	3	\$81	—	\$56	—
26	4	104	\$23	73	\$17
25	5	125	21	91	18
24	6	144	19	110	19
23	7	161	17	130	20
22	8	176	15	151	21

Step 3: Answer part (b) by determining the profit-maximizing quantity and price. We know that Comcast will maximize profit by selling subscriptions up to the point where marginal cost equals marginal revenue. In this case, that means selling 6 subscriptions per month. From the information in the

first two columns, we know Comcast can sell 6 subscriptions at a price of \$24 each. Comcast's profit is equal to the difference between its total revenue and its total cost: Profit = \$144 – \$110 = \$34 per month.

Step 4: Answer part (c) by analyzing the effect of the tax. The tax is a fixed cost to Comcast because it is a flat \$25 no matter how many subscriptions it sells. Because the tax doesn't affect Comcast's marginal revenue or marginal cost, the profit-maximizing level of output has not changed. So, Comcast will still sell 6 subscriptions per month at a price of \$24, but its profit will fall by the amount of the tax, from \$34 per month to \$9 per month.

Don't Let This Happen to You

Don't Assume That Charging a Higher Price Is Always More Profitable for a Monopolist

In answering part (c) of Solved Problem 15.3, it's tempting to argue that Comcast should increase its price to make up for the tax. After all, Comcast is a monopolist, so why can't it just pass along the tax to its customers? The reason it can't is that Comcast, like any other monopolist, must pay attention to demand. Comcast is not interested in charging high prices for the sake of charging high prices; it is interested in maximizing profit. Charging a price of \$1,000 per month for a basic cable subscription sounds nice, but if no one will buy at that price, Comcast would hardly be maximizing profit.

To look at it another way, before the tax is imposed, Comcast has already determined that \$24 per month is the price that will maximize its profit. After the tax is imposed, it must determine whether \$24 is still the profit-maximizing price. Because the tax has not affected Comcast's marginal revenue or marginal cost (or had any effect on consumer demand), \$24 is still the profit-maximizing price, and Comcast should continue to charge it. The tax reduces Comcast's profit but doesn't cause it to increase the price of cable subscriptions.

Does Monopoly Reduce Economic Efficiency?

LEARNING OBJECTIVE: Use a graph to illustrate how a monopoly affects economic efficiency.

We have seen that a perfectly competitive market is economically efficient (see Chapter 12). How would economic efficiency be affected if instead of being perfectly competitive, a market were a monopoly? *Economic surplus* provides a way of characterizing the economic efficiency in a market. *Equilibrium in a perfectly competitive market results in the greatest amount of economic surplus, or total benefit to society, from the production of a good or service* (see Chapter 4). What happens to economic surplus under a monopoly? We can begin the analysis by considering the hypothetical case of what would happen if the market for smartphones begins as perfectly competitive and then becomes a monopoly.

Comparing Monopoly and Perfect Competition

Panel (a) in Figure 15.4 illustrates the situation if the market for smartphones is perfectly competitive. Price and quantity are determined by the intersection of the demand and supply curves. Remember that none of the individual firms in a perfectly competitive industry has any control over price. Each firm must accept the price determined by the market. Panel (b) shows what happens if the smartphone market becomes a monopoly. We know that the monopoly will maximize profit by producing where marginal revenue equals marginal cost. To do this, the monopoly reduces the quantity

MyEconLab Animation

Figure 15.4 What Happens if a Perfectly Competitive Industry Becomes a Monopoly?

In panel (a), the market for smartphones is perfectly competitive, and price and quantity are determined by the intersection of the demand and supply curves. In panel (b), the perfectly competitive smartphone market becomes a monopoly. As a result, we have the following:

1. The industry supply curve becomes the monopolist's marginal cost curve.
2. The monopolist reduces output to where marginal revenue equals marginal cost, Q_M .
3. The monopolist raises the price from P_C to P_M .

of smartphones that would have been produced if the industry were perfectly competitive and increases the price. Panel (b) illustrates an important conclusion: *A monopoly will produce less and charge a higher price than would a perfectly competitive industry producing the same good.*

Measuring the Efficiency Losses from Monopoly

Figure 15.5 uses panel (b) from Figure 15.4 to illustrate how monopoly affects consumers, producers, and the efficiency of the economy. Recall that *consumer surplus*

MyEconLab Animation

Figure 15.5

The Inefficiency of Monopoly

A monopoly charges a higher price, P_M , and produces a smaller quantity, Q_M , than a perfectly competitive industry, which charges price P_C and produces Q_C . The higher price reduces consumer surplus by the area equal to the rectangle A and the triangle B. Some of the reduction in consumer surplus is captured by the monopoly as producer surplus, and some becomes deadweight loss, which is the area equal to triangles B and C.

measures the net benefit received by consumers from purchasing a good or service (see Chapter 4). We measure consumer surplus as the area below the demand curve and above the market price. The higher the price, the smaller the consumer surplus. Because a monopoly raises the market price, it reduces consumer surplus. In Figure 15.5, the loss of consumer surplus is equal to rectangle A plus triangle B. Remember that *producer surplus* measures the net benefit to producers from selling a good or service. We measure producer surplus as the area above the supply curve and below the market price. The increase in price due to monopoly increases producer surplus by an amount equal to rectangle A and reduces it by an amount equal to triangle C. Because rectangle A is larger than triangle C, we know that a monopoly increases producer surplus compared with perfect competition.

Economic surplus is equal to the sum of consumer surplus and producer surplus. By increasing price and reducing the quantity produced, the monopolist has reduced economic surplus by an amount equal to the areas of triangles B and C. This reduction in economic surplus is called *deadweight loss* and represents the loss of economic efficiency due to monopoly.

The best way to understand how a monopoly causes a loss of economic efficiency is to recall that price is equal to marginal cost in a perfectly competitive market. As a result, a consumer in a perfectly competitive market is always able to buy a good if she is willing to pay a price equal to the marginal cost of producing it. As Figure 15.5 shows, the monopolist stops producing smartphones at a point where the price is well above marginal cost. Consumers are unable to buy some smartphones for which they would be willing to pay a price greater than the marginal cost of producing them. Why doesn't the monopolist produce these additional smartphones? Because the monopolist's profit is greater if it restricts output and forces up the price. A monopoly produces the profit-maximizing level of output but fails to produce the efficient level of output from the point of view of society.

We can summarize the effects of monopoly as follows:

1. Monopoly causes a reduction in consumer surplus.
2. Monopoly causes an increase in producer surplus.
3. Monopoly causes a deadweight loss, which represents a reduction in economic efficiency.

[MyEconLab](#) [Concept Check](#)

How Large Are the Efficiency Losses Due to Monopoly?

We know that there are relatively few monopolies, so the loss of economic efficiency due to monopoly must be small. Many firms, though, have **market power**, which is the ability of a firm to charge a price greater than marginal cost. The analysis we just completed shows that some loss of economic efficiency will occur whenever a firm has market power and can charge a price greater than marginal cost, even if the firm is not a monopoly. The only firms that do *not* have market power are firms in perfectly competitive markets, which must charge a price equal to marginal cost. Because few markets are perfectly competitive, *some loss of economic efficiency occurs in the market for nearly every good or service.*

Is the total loss of economic efficiency due to market power large or small? It is possible to put a dollar value on the loss of economic efficiency by estimating for every industry the size of the deadweight loss triangle, as in Figure 15.5. The first economist to do this was Arnold Harberger of the University of California, Los Angeles. His estimates—largely confirmed by later researchers—indicated that the total loss of economic efficiency in the U.S. economy due to market power is relatively small. According to his estimates, if every industry in the economy were perfectly competitive, so that price were equal to marginal cost in every market, the gain in economic efficiency would equal less than 1 percent of the value of total production in the United States, or less than \$600 per person.

The loss of economic efficiency is this small primarily because true monopolies are very rare. In most industries, competition keeps price much closer to marginal cost than would be the case in a monopoly. The closer price is to marginal cost, the smaller the size of the deadweight loss.

[MyEconLab](#) [Concept Check](#)

Market power The ability of a firm to charge a price greater than marginal cost.

Market Power and Technological Change

Some economists argue that the economy may actually benefit from firms having market power. This argument is most closely identified with Joseph Schumpeter, an Austrian economist who spent many years as a professor of economics at Harvard. Schumpeter argued that economic progress depends on technological change in the form of new products. For example, the replacement of horse-drawn carriages by automobiles, the replacement of ice boxes by refrigerators, and the replacement of mechanical calculators by electronic computers all represent technological change that significantly raised living standards. In Schumpeter's view, new products unleash a "gale of creative destruction" that drives older products—and, often, the firms that produce them—out of the market. Schumpeter was not concerned that firms with market power would charge higher prices than perfectly competitive firms:

It is not that kind of [price] competition which counts but the competition from the new commodity, the new technology, the new source of supply, the new type of organization ... competition which commands a decisive cost or quality advantage and which strikes not at the margins of the profits and outputs of the existing firms but at their foundations and their very lives.

Economists who support Schumpeter's view argue that the introduction of new products requires firms to spend funds on research and development. It is possible for firms to raise this money by borrowing from investors or banks. But investors and banks are usually skeptical of ideas for new products that have not yet passed the test of consumer acceptance in the market. As a result, firms are often forced to rely on their profits to finance the research and development needed for new products. Because firms with market power are more likely to earn an economic profit than are perfectly competitive firms, they are also more likely to carry out research and development and introduce new products. In this view, the higher prices firms with market power charge are unimportant compared with the benefits from the new products these firms introduce to the market.

Some economists disagree with Schumpeter's views. These economists point to the number of new products developed by smaller firms, including, for example, Steve Jobs and Steve Wozniak inventing the first Apple computer in Jobs's garage, and Larry Page and Sergey Brin inventing the Google search engine as graduate students at Stanford. As we will see in the next section, government policymakers continue to struggle with the issue of whether, on balance, large firms with market power are good or bad for the economy.

15.5 Government Policy toward Monopoly

LEARNING OBJECTIVE: Discuss government policies toward monopoly.

Because monopolies reduce consumer surplus and economic efficiency, most governments have policies that regulate their behavior. **Collusion** refers to an agreement among firms to charge the same price or otherwise not to compete (see Chapter 14). The European Union (EU) *competition law* is designed to prevent monopolies and anti-competitive practices. Governments also regulate firms that are natural monopolies, often by controlling the prices they charge.

Competition Laws and Antitrust Enforcement

The British *common law of restraint of trade* that dates back to the fifteenth century is the actual predecessor to modern European competition law. After the United States enacted the Sherman Act of 1890 it has become the pioneer of modern laws regulating monopolies. Modern European competition law was briefly recognized during the inter-war period, only to disappear again at the onset of the Great Depression of 1929. Under pressures from the United States, the United Kingdom and Germany became the first European countries to adopt full-fledged competition laws.

Collusion An agreement among firms to charge the same price or otherwise not to compete.

Agreement or Treaty	Date Enacted	Purpose
Treaty of Rome	1957	The six countries of the ECSC signed the Treaty of Rome setting up the European Economic Community (EEC). The EEC aimed to prohibit anti-competitive agreements, the abuse of dominant position, public undertakings, and unlawful state aid.
ECSC	1951	The ECSC aimed to further economic integration among its member states, remove barriers to the internal market for coal and steel, manage the modernization of production and prevent the re-emergence of cartels.
Treaty on the Functioning of the European Union	2007	TFEU prohibits anti-competitive agreements, price fixing, abuse of dominant position, and aid or subsidies to private or public firms violating free competition.

Table 15.1

Timeline of the EU Competition Law

Considering the German near monopoly over coal and steel production as the main factor behind the outbreak of the Second World War (WWII), the European Coal and Steel Community (ECSC) agreement was signed between France, Italy, Belgium, Holland, Luxembourg, and Germany in 1951. The EU competition law has its origins in the ECSC. Articles 65 and 66 of the ECSC banned cartels, but made provisions for mergers, concentrations, and the abuse of dominant positions. In 1957 the Treaty of Rome enacted the competition law as one of the main aims of the European Economic Community through the “institution of a system ensuring that competition in the common market is not distorted.”

Article 85 of the Treaty of Rome prohibited anti-competitive arrangements, Article 86 prohibited the abuse of dominant position, Article 90 covered public undertakings, and Article 92 made provisions on state aid. Since EU member nations were unable to reach consensus, the Treaty of Rome did not include regulations on mergers. Since its enactment in 2007, the EU competition law today derives from articles 101 to 109 of the Treaty on the Functioning of the European Union (TFEU) in addition to a series of Regulations and Directives of the European Council. The task of tracking down and penalizing private firms or public enterprises that breach of the EU competition law has been entrusted to the European Commission, which receives its powers under Article 105 of the TFEU.

Article 101 of the TFEU prohibits anti-competitive agreements and price fixing. Article 102 prohibits the abuse of dominant position, such as price discrimination and exclusive dealing. Articles 106 and 107 provide that public enterprises must adhere to the same competition principles as private firms. Article 107 stipulates that the state may not extend financial aid or subsidies to private or public firms that violate free competition. For example, on 9 January 2012, the European Commission considered the state aid received by MALEV, the Hungarian flag carrier airliner, illegal. It ordered Hungary to recover from the company the state aid totaling €130 million. MALÉV was declared insolvent in 2012. Table 15.1 lists the time line of the EU competition law.

Did Apple Violate the Law in Pricing e-Books?

People who buy e-books got some bad news in 2010 when Apple introduced the iPad: The prices of new books and best sellers increased from \$9.99 to \$12.99 or \$14.99. The price increases were not just for books sold in Apple's iBooks Store but also for books Amazon was selling for its Kindle. Why did this big jump in prices happen? The U.S. Justice Department had a straightforward answer: Apple had organized an agreement

Did Apple illegally restrict competition to raise the prices of e-books?

with five large book publishers to raise the prices of e-books. As one Justice Department lawyer put it, Apple had directed “an old-fashioned, straight-forward price-fixing agreement.” Accordingly, the Justice Department sued Apple for violating the antitrust laws. The lawsuit was a civil action, meaning that the Justice Department was not pursuing criminal charges against Apple executives.

When Amazon introduced its Kindle e-reader in 2007, it priced most new books and best sellers at \$9.99, even though this price was less than the price the publishers were charging Amazon for the books. Amazon believed that by selling e-books at a loss, it would increase sales of the Kindle. Most publishers were unhappy with Amazon’s low e-book prices, however, because they believed the prices reduced sales of hardcover copies of best sellers on which the publishers made a larger profit. According to the Justice Department, Apple took advantage of the publishers’ unhappiness to propose an “agency pricing model.” Under

this model, the publishers would set the retail price of e-books, and Apple would keep 30 percent of the price of every e-book it sold.

In addition, Apple negotiated a clause in its contracts with the publishers that allowed Apple to match the retail prices of other e-book sellers. By invoking this clause, Apple would be able to sell e-books for \$9.99 if Amazon continued to do so. The publishers then insisted that Amazon switch to an agency pricing model. If Amazon failed to switch, the publishers said they would not allow Amazon to sell electronic versions of their books until months after the hardcover editions were first published, which would give Apple a huge advantage in the e-book market. Faced with this situation, Amazon also adopted the agency pricing model, and the publishers were able to raise the prices of most new books to \$12.99 or \$14.99.

At the trial, Apple argued that it had not attempted to organize a price-fixing agreement with the publishers. Instead, Apple had simply proposed a pricing model similar to the one it was already using for songs in its iTunes store. As Apple’s executive in charge of negotiating with the publishers put it, “I didn’t raise prices. The publishers set the prices.” Representatives of the publishers also testified during the trial that they had not conspired with Apple or with each other to fix the prices of e-books.

In the end, a judge ruled that Apple had conspired with the publishers to raise e-book prices. Following the decision, the Justice Department proposed that the judge bar Apple from entering agency pricing contracts with publishers for a period of five years. Apple appealed the judge’s decision, and in 2015 an appeals court agreed that Apple had violated the law. One of the justices dissented, though, arguing, “Apple took steps to compete with a monopolist and open the market to more entrants, generating only minor competitive restraints in the process.” The Justice Department disagreed with this analysis and welcomed the decision, asserting, “Because Apple and the defendant publishers sought to eliminate price competition in the sale of e-books, consumers were forced to pay higher prices for many e-book titles.” Apple appealed the decision to the U.S. Supreme Court.

The lawsuit the Justice Department brought against Apple is an example of attempts by the government to keep firms from artificially restricting competition to raise prices. As we have seen, higher prices reduce consumer surplus and economic efficiency.

Mergers: The Trade-off between Market Power and Efficiency

The federal government regulates business mergers because if firms gain market power by merging, they may use that market power to raise prices and reduce output. As a result, the government is most concerned with **horizontal mergers**, or mergers between firms in the same industry. Two airlines or two candy manufacturers merging are examples of a horizontal merger. Horizontal mergers are more likely to increase market power than **vertical mergers**, which are mergers between firms at different stages of the production of a good. An example of a vertical merger would be a merger between a company making soft drinks and a company making plastic bottles.

Federal regulators deal with two factors that can complicate evaluating horizontal mergers:

1. **The extent of the market.** The “market” that firms are in is not always clear. For example, if Hershey Foods wants to merge with Mars, Inc., maker of M&Ms, Snickers, and other candies, what is the relevant market?
 - If the government looks just at the candy market, the newly merged company would have more than 70 percent of the market, a level at which the government would likely oppose the merger.
 - If the government looks at the broader market for snacks, Hershey and Mars compete with makers of potato chips, pretzels, and peanuts—and perhaps even producers of fresh fruit. With this broader definition of the market, the market shares of Hershey and Mars would likely be too low for federal regulators to oppose their merger.
 - If the government looked at the very broad market for food, then both Hershey and Mars have very small market shares, and there would be no reason for federal regulators to oppose their merger.

In practice, the government defines the relevant market on the basis of whether there are close substitutes for the products being made by the merging firms. In this case, potato chips and the other snack foods mentioned are not close substitutes for candy. So, the government would consider the candy market to be the relevant market and would oppose the merger, on the grounds that the new firm would have too much market power.

2. **Possible increases in economic efficiency.** The second factor that complicates merger policy is the possibility that the newly merged firm might be more efficient than the merging firms were individually. For example, one firm might have an excellent product but a poor distribution system for getting the product into the hands of consumers. A competing firm might have built a great distribution system but have an inferior product. Allowing these firms to merge might be good for both the firms and consumers. Or, two competing firms might each have an extensive system of warehouses that are only half full, but if the firms merged, they could consolidate their warehouses and significantly reduce their average costs.

Most of the mergers that come under the scrutiny of the Department of Justice and the FTC are between large firms. For simplicity, though, let’s consider a case in which all the firms in a perfectly competitive industry want to merge to form a monopoly. As we saw in Figure 15.5 on page 570, as a result of this merger, prices will rise and output will fall, leading to a decline in consumer surplus and economic efficiency. But what if the larger, newly merged firm actually is more efficient than the smaller firms were? Figure 15.6 shows a possible result.

If the merger doesn’t affect costs, we have the same result as in Figure 15.5: Price rises from P_C to P_M , quantity falls from Q_C to Q_M , consumer surplus declines, and there is a loss of economic efficiency. If the monopoly has lower costs than the competitive firms, it is possible for price to decline and quantity to increase. In Figure 15.6, note that after the merger MR crosses MC at the new profit-maximizing quantity, Q_{Merge} . The demand curve shows that the monopolist can sell this quantity of the good at a price of P_{Merge} . Therefore, the price declines after the merger from P_C to P_{Merge} , and the quantity

Horizontal merger A merger between firms in the same industry.

MyEconLab Animation

Figure 15.6 A Merger That Makes Consumers Better Off

This figure shows the result of all the firms in a perfectly competitive industry merging to form a monopoly. If the merger does not affect costs, the result is the same as in Figure 15.5 on page 570: Price rises from P_C to P_M , quantity falls from Q_C to Q_M , consumer surplus declines, and a loss of economic

efficiency results. If, however, the monopoly has lower costs than the perfectly competitive firms, as shown by the marginal cost curve shifting to MC after the merger, it is possible that the price of the good will actually decline from P_C to P_{Merge} and that output will increase from Q_C to Q_{Merge} following the merger.

increases from Q_C to Q_{Merge} . We have the following seemingly paradoxical result: *The newly merged firm has a great deal of market power, but consumers are better off and economic efficiency is increased because the firm is more efficient.* Of course, sometimes a merged firm will be more efficient and have lower costs, and other times it won't. Even if a merged firm is more efficient and has lower costs, the lower costs may not offset the increased market power of the firm enough to increase consumer surplus and economic efficiency.

As you might expect, whenever large firms propose a merger, they claim that the newly merged firm will be more efficient and have lower costs. They realize that without these claims, the Department of Justice and the FTC, along with the court system, are unlikely to approve the merger.

MyEconLab Concept Check

European Court of Justice and European Council Merger Guidelines

For over six decades, the European Council and the European Court have been enforcing the EU competition law in the hope that excessive concentration would lessen competition, which may raise prices and reduce consumer welfare. Lawyers of the European Court paid little attention to the economic implications of merger prohibitions. For example, consumers might be made better off if mergers produce sufficient efficiency gains. In order to bring benefits to consumers and the economy, the EC hires economists to gauge the economic consequences of proposed mergers. As such, Council Regulation (EEC) No. 4064/89 of December, 1989, which was replaced by Regulation (EC) No. 139/2004 on January, 2004, had been passed to prohibit only those concentrations and mergers that impede effective competition.

EC economists compare the competitive conditions that would result from prospective mergers with those that would have prevailed without the merger. The EC's

assessment of mergers is quite similar to the guidelines of the U.S. Department of Justice and the Federal Trade Commission. The U.S. guidelines were modified in 2010 and have three main parts:

1. Market definition
2. Measure of concentration
3. Merger standards

Market Definition A market consists of all firms making products that consumers view as close substitutes. Economists can identify close substitutes by looking at the effect of a price increase. If the definition of a market is too narrow, a price increase will cause firms to experience a significant decline in sales—and profits—as consumers switch to buying close substitutes.

Identifying the relevant market involved in a proposed merger begins with a narrow definition of the industry. For a hypothetical merger of Hershey Foods and Mars, Inc., economists might start with the candy industry. If all firms in the candy industry increased price by 5 percent, would their profits increase or decrease? If profits would increase, the market is defined as being just these firms. If profits would decrease, economists would try a broader definition—say, by adding in potato chips and other snacks. Would a price increase of 5 percent by all firms in the broader market raise profits? If profits increase, the relevant market has been identified. If profits decrease, economists consider a broader definition. Economists continue the process until a market has been identified.

Measure of Concentration A market is *concentrated* if a relatively small number of firms have a large share of total sales in the market. A merger between firms in a market that is already highly concentrated is very likely to increase market power. A merger between firms in an industry that has a very low concentration is unlikely to increase market power and can be ignored. The guidelines use the *Herfindahl-Hirschman Index (HHI)* of concentration, which squares the market shares of each firm in the industry and adds up the values of the squares. The following are some examples of calculating HHI:

- 1 firm, with 100 percent market share (a monopoly):

$$\text{HHI} = 100^2 = 10,000.$$

- 2 firms, each with a 50 percent market share:

$$\text{HHI} = 50^2 + 50^2 = 5,000.$$

- 4 firms, with market shares of 30 percent, 30 percent, 20 percent, and 20 percent:

$$\text{HHI} = 30^2 + 30^2 + 20^2 + 20^2 = 2,600.$$

- 10 firms, each with a 10 percent market share:

$$\text{HHI} = 10 \times (10)^2 = 1,000.$$

Merger Standards Table 15.2 shows how the Department of Justice and the FTC use the HHI calculation for a market to evaluate proposed horizontal mergers according to these standards.

The merger guidelines state that increases in economic efficiency will be taken into account and can lead to approval of a merger that otherwise would be opposed, but the burden of showing that the efficiencies exist lies with the merging firms:

The merging firms must substantiate efficiency claims so that the [Department of Justice and the FTC] can verify by reasonable means the likelihood and magnitude of each asserted efficiency. . . . Efficiency claims will not be considered if they are vague or speculative or otherwise cannot be verified by reasonable means.

Regulating Natural Monopolies

If a firm is a natural monopoly, competition from other firms will not play its usual role of forcing price down to the level where the company earns zero economic profit. As a result, local or state *regulatory commissions* usually set the prices for natural monopolies, such as firms selling natural gas or electricity. What price should these commissions set? Economic efficiency requires the last unit of a good or service produced to provide an additional benefit to consumers equal to the additional cost of producing it (see Chapter 11). We can measure the additional benefit consumers receive from the last unit by the price of the product, and we can measure the additional cost to the monopoly of producing the last unit by marginal cost. Therefore, to achieve economic efficiency, regulators should require that the monopoly charge a price equal to its marginal cost. There is, however, an important drawback to doing so, as illustrated in Figure 15.7, which shows the situation of a typical regulated natural monopoly.

MyEconLab Animation

Figure 15.7 Regulating a Natural Monopoly

A natural monopoly that is not subject to government regulation will charge a price equal to P_M and produce Q_M . If government regulators want to achieve economic efficiency, they will set the regulated price equal to P_E , and the monopoly will produce Q_E . Unfortunately, P_E is below average total

cost, and the monopoly will suffer a loss, shown by the red rectangle. Because the monopoly will not continue to produce in the long run if it suffers a loss, government regulators set a price equal to average total cost, which is P_R in the figure. The resulting production, Q_R , will be below the efficient level.

Remember that with a natural monopoly, the average total cost curve is still falling when it crosses the demand curve. If unregulated, the monopoly will charge a price equal to P_M and produce Q_M . To achieve economic efficiency, regulators should require the monopoly to charge a price equal to P_E . The monopoly will then produce Q_E . But here is the drawback: P_E is less than average total cost, so the monopoly will be suffering a loss, shown by the area of the red-shaded rectangle. In the long run, the owners of the monopoly will not continue in business if they are experiencing a loss. Realizing this, most regulators will set the regulated price, P_R , equal to the level of average total cost at which the demand curve intersects the ATC curve. At that price, the owners of the monopoly are able to break even on their investment by producing the quantity Q_R , although this quantity is below the efficient quantity, Q_E .

What Should Your College Charge for a MOOC?

In Chapter 11, we observed that some colleges offer massive open online courses (MOOCs). We saw that the fixed cost of an online course is relatively high because instructors must develop new syllabi, exams, and teaching notes, as well as determine when and how to interact with their students. But after the course is placed online, the marginal cost of providing instruction to an additional student is low and will be constant rather than U shaped. Suppose that your college decides to offer a calculus course as a MOOC that can be taken by students anywhere in the world, whether they are actually enrolled in your college or not. The figure shows the demand and cost situation for the MOOC:

- The faculty member who designed the course argues: "I think the course should be priced so that the maximum number of students enroll." Which price should this faculty member favor? Briefly explain.
- An economics professor argues: "I think the course should be priced so as to achieve economic efficiency." Which price should this faculty member favor? Briefly explain.
- The dean of the college argues: "I think the course should be priced to maximize the profit the college earns, so these funds can be used to pay some other expenses." Which price should the dean favor? Briefly explain.
- You are a member of a student committee that is asked to recommend a price for the course and you argue: "I think the college should charge a price so that it just breaks even on the course." What price should you recommend? Briefly explain.
- How much profit (or loss) will the college make on the course if it charges each of the prices you found in your answers to parts (a), (b), (c), and (d)?

Solving the Problem

Step 1: Review the chapter material. This problem is related to the discussion of pricing in a situation of natural monopoly, so you may want to review the section "Regulating Natural Monopolies," which begins on page 578.

Step 2: Begin your answer by noting that the situation in the figure is similar to the situation of a natural monopoly, as shown in Figure 15.7. Because the graph shows the average total cost curve for the MOOC as still falling when it crosses the demand curve, effectively this MOOC is a natural monopoly, and we can employ the analysis of prices shown in Figure 15.7 to answer the questions.

- Step 3:** Answer part (a) by explaining which price will maximize the number of students enrolling in the course. The graph shows that the maximum number of students to take the course will occur when the price equals 0 and the demand curve intersects the quantity axis.
- Step 4:** Answer part (b) by explaining which price will result in economic efficiency. Economic efficiency occurs where price equals marginal cost. In the graph, the price should be set at \$20 to achieve economic efficiency.
- Step 5:** Answer part (c) by explaining which price will maximize the profit the college will earn from the course. To maximize profit, the college should charge a price that results in a quantity demanded at which marginal revenue equals marginal cost. In the graph, the price that maximizes profit equals \$75.
- Step 6:** Answer part (d) by explaining which price will result in the college just breaking even on the course. To break even, the college should charge a price equal to average total cost. In the graph, at a price of \$44, price is equal to average total cost, and the college just breaks even on the course.
- Step 7:** Answer part (e) by calculating the profit (or loss) the college will make if it charges each of the prices you found in the earlier parts of the problem. The following table shows the calculation of profit (or loss) for each price.

If the college charges this price . . .	it will earn revenue of . . .	and have a total cost equal to . . .	So, the college will . . .
0	0	the average total cost of \$36 per student multiplied by the 24,000 students who enroll, or $\$36 \times 24,000 = \$864,000$.	suffer a loss of $0 - \$864,000 = -\$864,000$.
\$20	$\$20 \times 20,000 = \$400,000$	$\$38 \times 20,000 = \$760,000$.	suffer a loss of $\$400,000 - \$760,000 = -\$360,000$.
\$75	$\$75 \times 10,000 = \$750,000$	$\$60 \times 10,000 = \$600,000$.	earn a profit of $\$750,000 - \$600,000 = \$150,000$.
\$44	$\$44 \times 16,000 = \$704,000$	$\$44 \times 16,000 = \$704,000$.	break even.

Economics in Your Life

Can a Business Run from of Your Dorm Be a Monopoly?

At the beginning of the chapter, we asked whether the submarine sandwich business you and your roommate, Fatma, start in your dorm was a monopoly and whether you should charge high prices for the subs to increase your profit. In this chapter, we have seen that a monopoly is a firm that is the only seller of a good or service that does not have a close substitute. Even though you and Fatma would be the only sellers of submarine sandwiches on campus during the evening hours of Saturdays and Sundays, there could be other options for hungry students. For example, students could buy food from nearby off-campus restaurants, have food delivered from those restaurants, or buy from on-campus vendors that are open earlier in the day. Most goods have substitutes, and you and Fatma should realize that for many students, pizza and hamburgers from local restaurants are good substitutes for subs. High prices are likely to lead many of your customers to search for those substitutes.

Conclusion

The more intense the level of competition among firms, the better a market works. In this chapter, we have seen that, compared with perfect competition, in a monopoly, the price of a good or service is higher, output is lower, and consumer surplus and economic efficiency are reduced. Fortunately, true monopolies are rare. Even though most firms resemble monopolies in being able to charge a price above marginal cost, most markets have enough competition to keep the efficiency losses from market power low.

Is Any Firm Ever Really a Monopoly? pages 558–560

LEARNING OBJECTIVE: Define monopoly.

Summary

A **monopoly** exists only in the rare situation in which a firm is producing a good or service for which there are no close substitutes. A narrow definition of monopoly that some economists use is that a firm has a monopoly if it can ignore the actions of all other firms. Many economists favor this broader definition of monopoly: A firm has a monopoly if no other firms are selling a substitute close enough that the firm's economic profit is competed away in the long run.

Review Questions

- 1.1 What is a monopoly? Can a firm be a monopoly if close substitutes for its product exist?
- 1.2 Why are there two definitions of a monopoly, a narrow and a broader one?

Problems and Applications

- 1.3 Some claim that Microsoft is a monopolist because of the Windows operative system: there are no close substitutes for this product and, therefore, Microsoft enjoys positive profits despite making mistakes at times. For example, Windows Vista has been negatively assessed by most users. Do you agree? Briefly explain your answer.
- 1.4 In a column in the *Wall Street Journal*, venture capitalist Peter Thiel described the difference between monopoly businesses and competitive ones: "Suppose you want to start a restaurant in Palo Alto that serves British food.

'No one else is doing it,' you might reason. 'We'll own the entire market.' Would the only restaurant that sells British food in Palo Alto, or any other city, be considered a monopoly? What criteria would you use to determine whether the restaurant is a monopoly?
